LESSON 1 8-SPEED OVERVIEW AND LIGHT MAINTENANCE

8-SPEED GENERAL SPECIFICATIONS

8-Speed Overview

2034-81_0001

Figure 1 Transmission Overview

The 8HP45 is an electronic, 8-speed, automatic transmission that incorporates state-of-the-art technology. The transmission control module assembly (TCMA), which is integrated into the valve body, provides fully synchronized clutch-to-clutch shifting through four planetary gear sets. The valve body assembly contains all the sensors and solenoids required for operation completely inside the transmission. This 8-speed transmission offers distinct advantages over 6-speed transmissions by providing additional ratios for even quicker acceleration and shorter shift intervals. Eight speeds allow the engine to maintain its optimal rpm range, increasing fuel economy and performance.

8-Speed Overview and Light Maintenance

Introduction to Shifters

Figure 2 Shifter Designs

There are two main shifter designs used with the 8-speed automatic transmission: conventional and rotary. Both shifter designs are shift-by-wire and park-by-wire. There is no mechanical connection between the transmission and the shifter. Range selection is provided to the transmission control module (TCM) over a CAN network. Both shifter designs can be equipped with AutoStick. Park-by-wire parking pawl control is provided by a combination of hydraulic and electrical solenoids. Because these shifters are not mechanically connected to the transmission, a manual park release is provided.

Conventional Lever Shifter Design

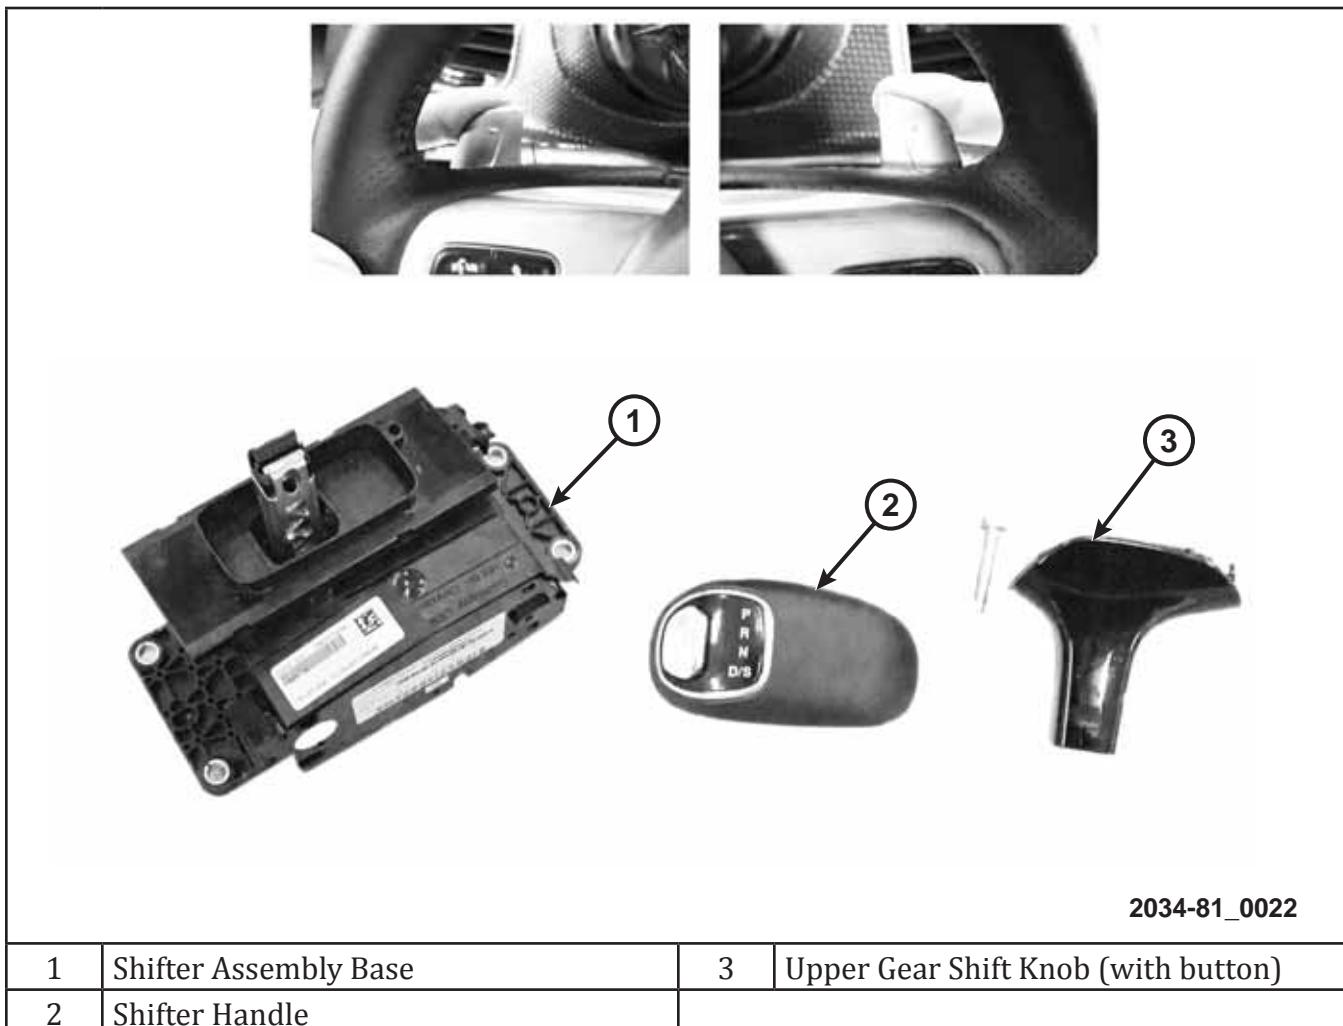

Figure 3 Electronic Shifter Assembly

Gear range selection on the 8-speed automatic transmission is accomplished using an electronic shifter. The electronic shifter system uses sensors and network communication with the TCM instead of a traditional cable. The image shows current serviceable parts for the conventional lever electronic shifter.

The base shifter displays a typical PRNDL pattern, where the low position limits the top gear and provides additional engine braking.

The up-level shifter displays a PRNDS pattern, where the S stands for sport. In the sport position, a more aggressive feeling shift pattern is applied. The sport shifter is always paired with paddle-shift buttons on the steering wheel that operate similar to AutoStick. The paddle-shift switches communicate through the steering column control module (SCCM) on the CAN-C network.

Vehicles equipped with the 8-speed automatic transmission are also equipped with a brake transmission interlock (BTI). The BTI requires the driver to apply the brakes before the vehicle can be shifted out of park.

8-Speed Overview and Light Maintenance

Conventional Lever Shifter Assembly

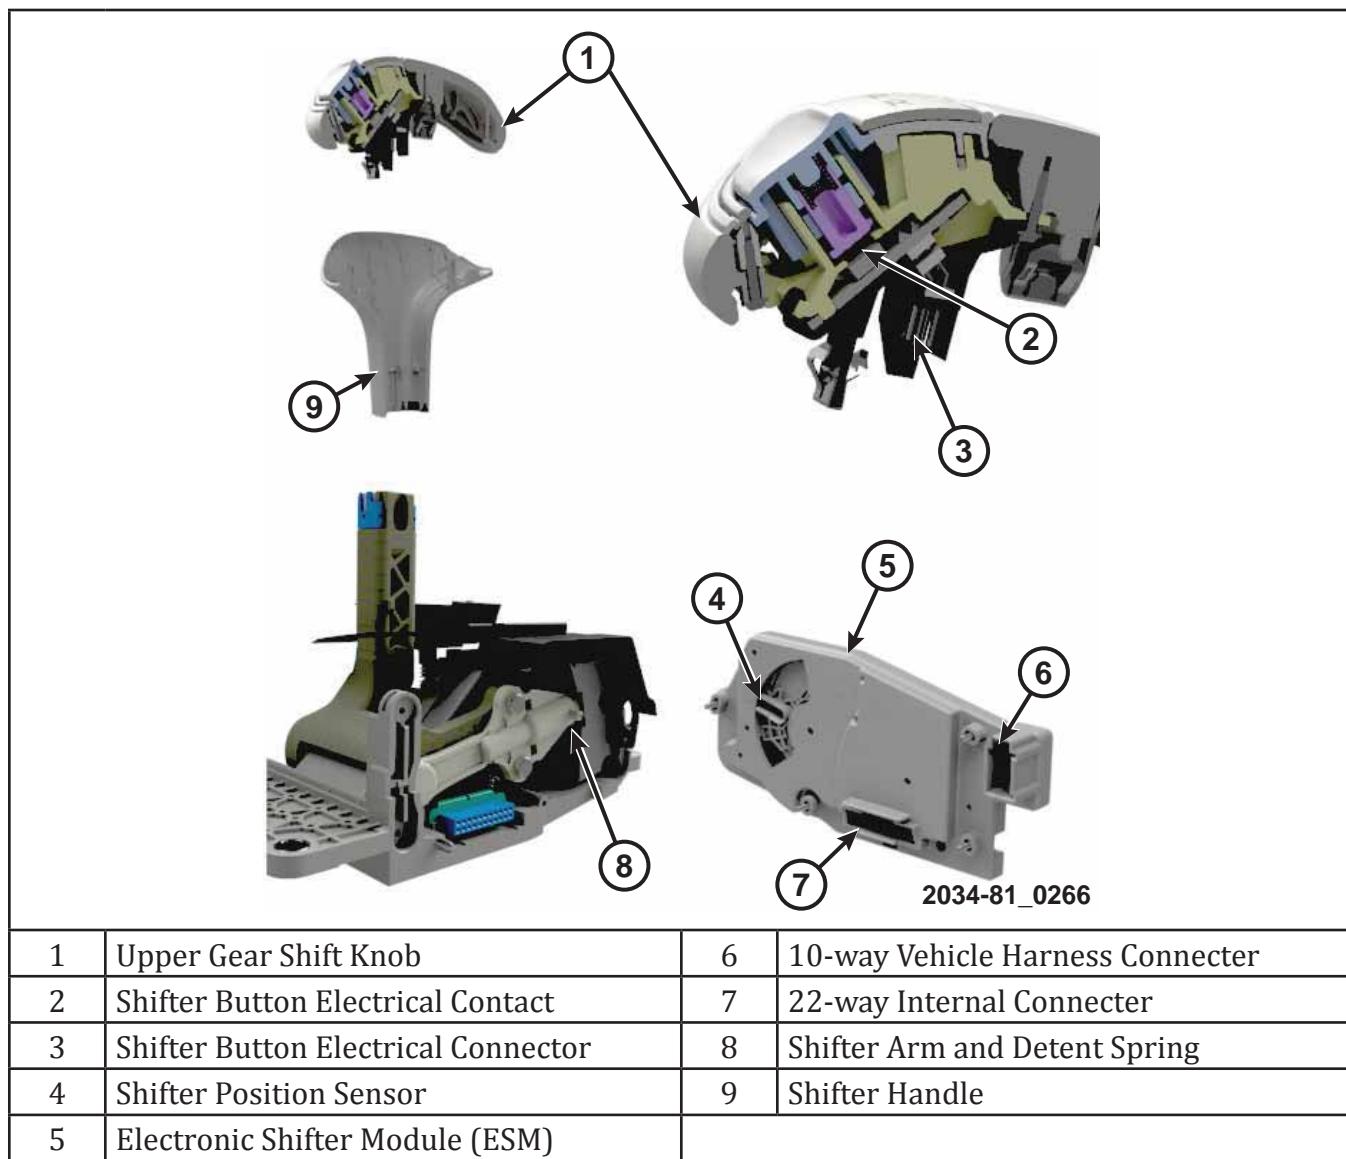

Figure 4 Shifter Cut Away View

Shifter in Drive Position

The transmission functions automatically until the paddles are used. The TCM responds to paddle requests. After a certain amount of time, or coming to a stop, the TCM returns to fully automatic mode.

Shifter in Sport Position

The transmission functions automatically with a more aggressive shift schedule. After the first press of either paddle, the transmission functions like AutoStick, waiting for a command before shifting. The driver can return to fully automatic mode by pressing and holding the + shifter paddle or shifting to a different gate.

Rotary Shifter Assembly

L01_001

Figure 5 Rotary Shifters

The rotary e-shifter operates similarly to the conventional lever shifter. The rotary e-shifter is an all-in-one switch and module that includes provisions for the brake transmission shifter interlock (BTSD). The rotary e-shifter can be dash- or console-mounted. The use of this shifter requires the use of a mechanical release for service and towing. Current shifter position will be indicated on the rotary shifter by an illuminated LED as well as shown in the instrument panel cluster. The LEDs on the rotary shifter will also flash in the event of certain malfunctions.

8-Speed Overview and Light Maintenance

Park Lock System

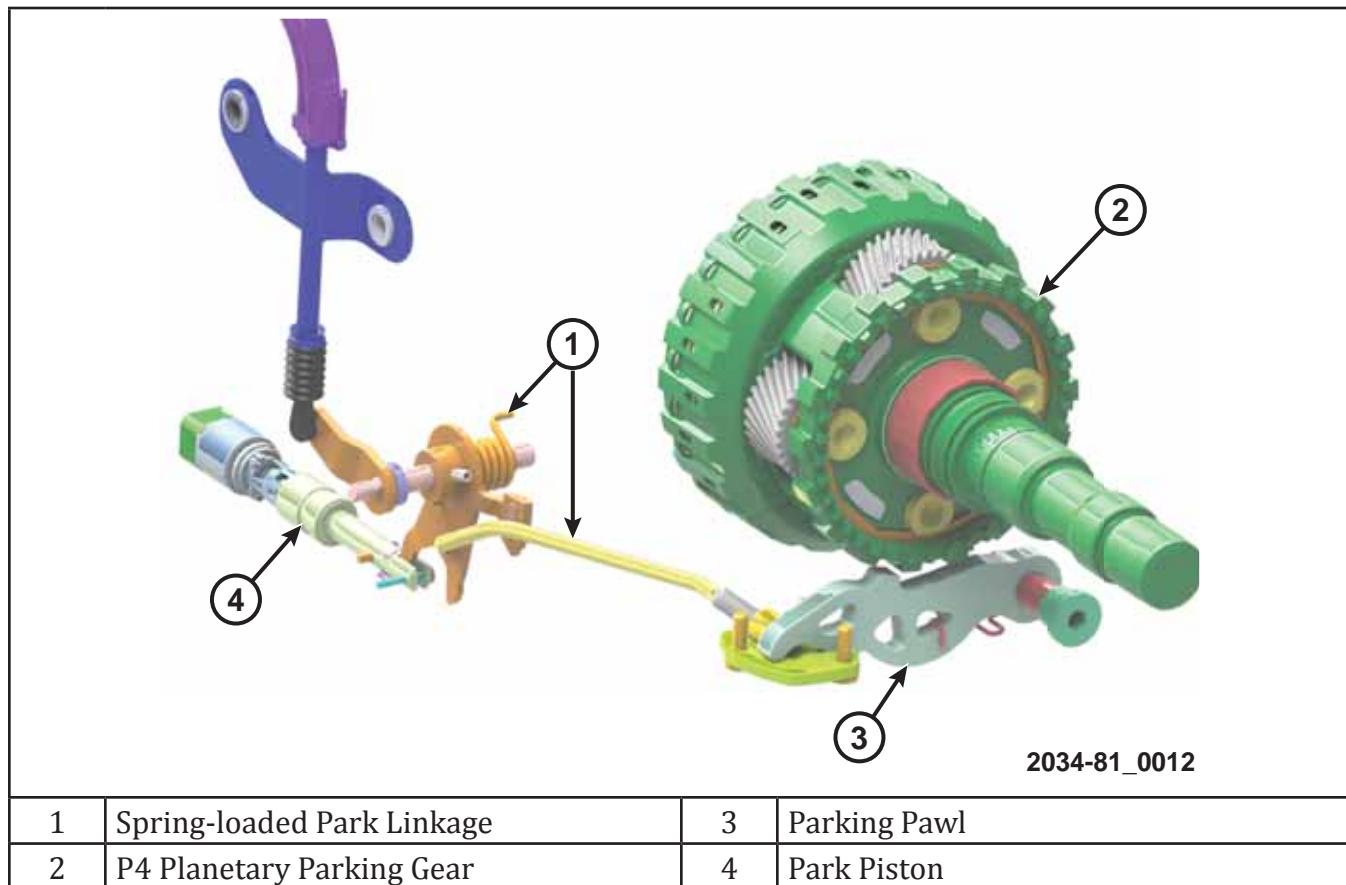

Figure 6 Park Lock System

The transmission uses a shift-by-wire system, so there is no mechanical connection between the shifter and the transmission. The transmission uses a park lock piston to control the position of the parking pawl. The park linkage inside the transmission is similar to previous designs; however, this linkage is spring-loaded to default into the park position. The parking pawl engages into the teeth of the parking gear on the P4 carrier to prevent movement.

Manual Park Release

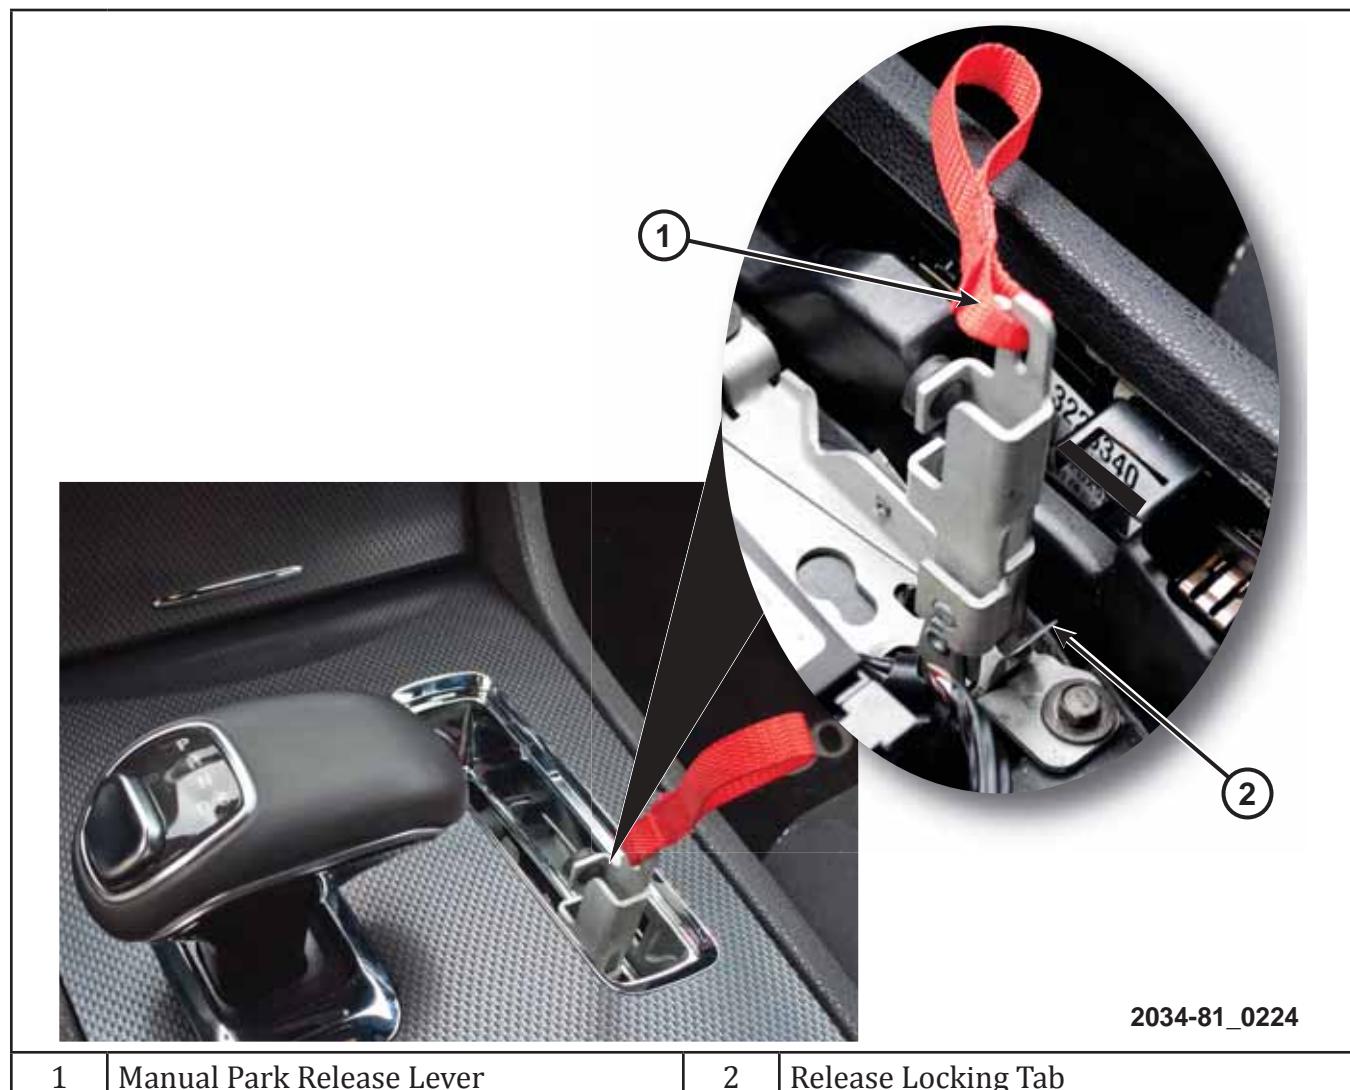

Figure 7 Manual Park Release Operation

In the event of a complete transmission electrical failure, the transmission park pawl is engaged when the engine is off. For this reason, the transmission is equipped with a manual park release lever.

Pictured above is the manual park release for a Chrysler 300. Refer to service information for the location of the manual park release for other vehicles. The lever is located under the shift console and can be accessed by removing the storage tray to the right of the shifter. When the cable is pulled, the release cable pulls upward on the release lever, which releases the park lock spring jack and allows the park pawl to disengage from the parking gear.

8-Speed Overview and Light Maintenance

8-SPEED MAINTENANCE AND LIGHT SERVICE

Valve Body Assembly

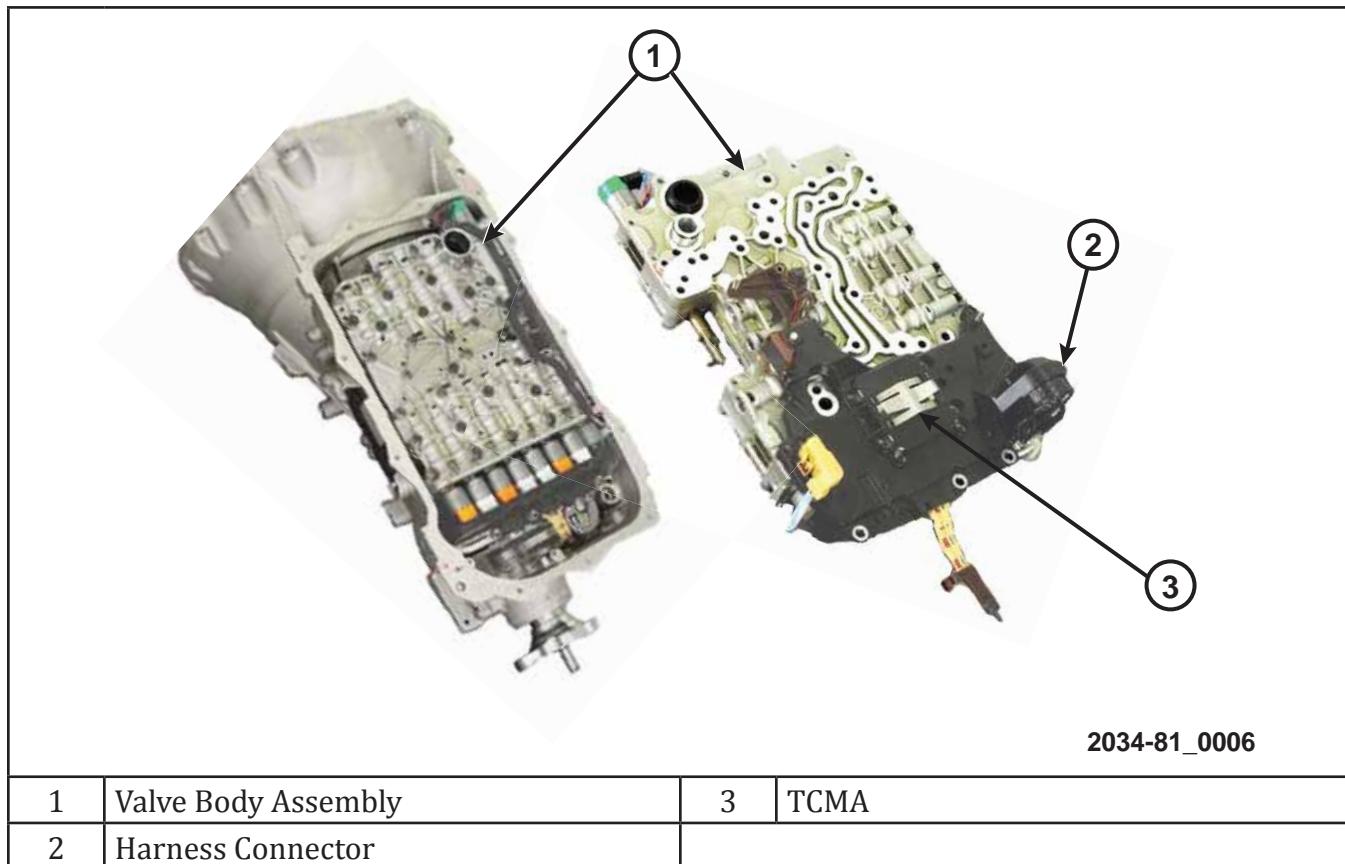

Figure 8 Valve Body Assembly

The valve body assembly is comprised of the valve body and the transmission control module assembly (TCMA). The valve body and TCMA are serviced as an assembly.

Stop/Start Fluid Accumulator

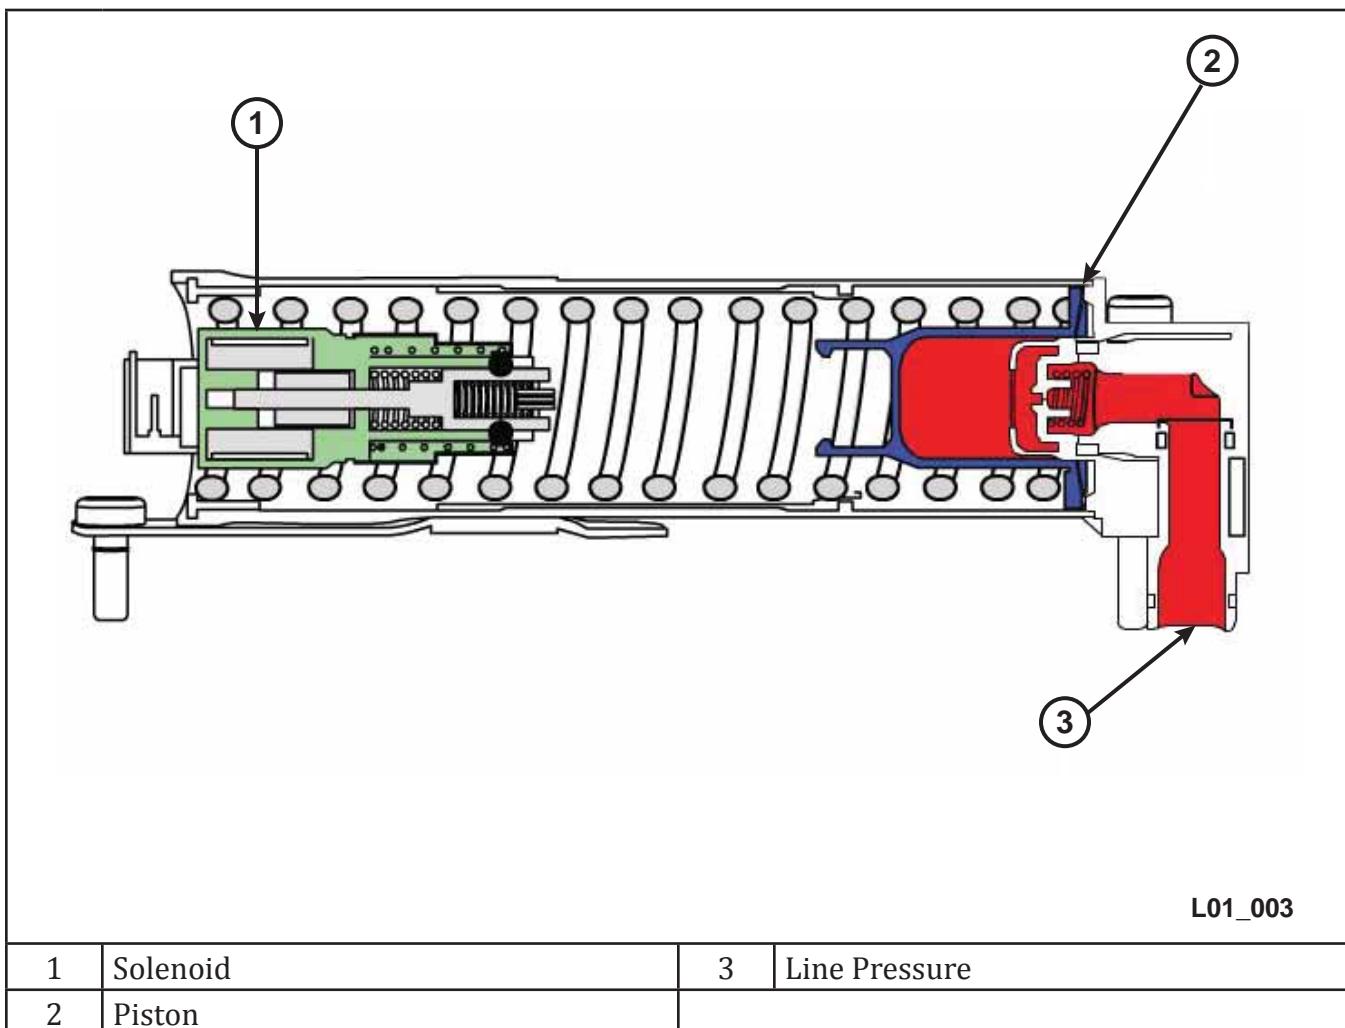

Figure 9 Stop/Start Fluid Accumulator

Vehicles equipped with an 8-speed transmission can be equipped with stop/start technology. If an 8-speed transmission is equipped with the start/stop feature, a hydraulic impulse storage (HIS) accumulator is integrated in the valve body to support the stop/start feature. When the engine is stopped, a conventional transmission loses hydraulic pressure; additional time is then needed to restore transmission operating pressure after the engine restarts. The hydraulic accumulator stores pressurized oil, supplements the pump, and maintains transmission pressures, eliminating pressure buildup time and clutch engagement delay. The HIS oil storage unit utilizes a spring piston accumulator charged by the oil pump. When the accumulator is fully charged, an electronic solenoid holds pressurized fluid until the TCM commands the solenoid to release the fluid. When the engine auto starts, the oil charge is promptly released, supplying the hydraulic valves and clutches with pressurized oil, and the vehicle is ready to move instantly. Without the HIS, a detectable delay in vehicle acceleration would exist, leading to a loss in driving dynamics.

8-Speed Overview and Light Maintenance

Fluid Type and Pan Design

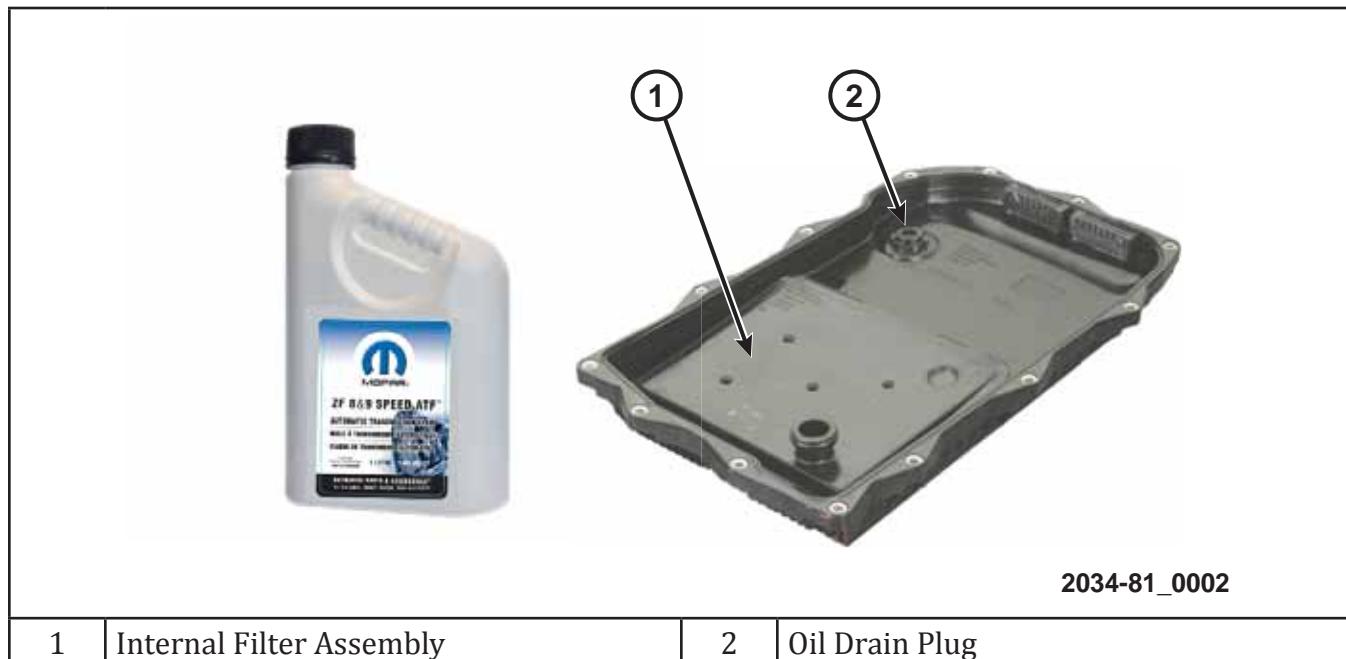

Figure 10 Fluid Type

A special automatic transmission fluid (ATF) is required, and a unique oil fill procedure must be followed to properly add fluid after transmission service. ATF+4 is NOT compatible with the 8-speed automatic transmission and should not be used under any circumstance.

The 8-speed automatic transmission has a filled-for-life transmission fluid strategy. The transmission is filled at the factory once and, under normal operating conditions, it is not necessary to check the fluid level or change the fluid and filter. Be aware that there may be fluid service requirements for severe duty applications, such as taxi or fleet vehicles. Refer to service information for the maintenance schedule.

NOTE: **Mopar oil leak dye has not been approved for use with the 8- and 9-speed automatic transmission fluid. Do not add any fluid other than the approved ATF. Unless otherwise specified, use leak trace powder as an alternative.**

The fluid filter is an integral part of the oil pan and cannot be replaced separately. The filter is only replaced when performing repairs to the transmission.

CAUTION: **To avoid damage to the plastic oil pan, do not support the weight of the transmission in the center of the oil pan. The supports for the jack should be placed around the edge of the pan or rail.**

Fluid Level Check and Fill

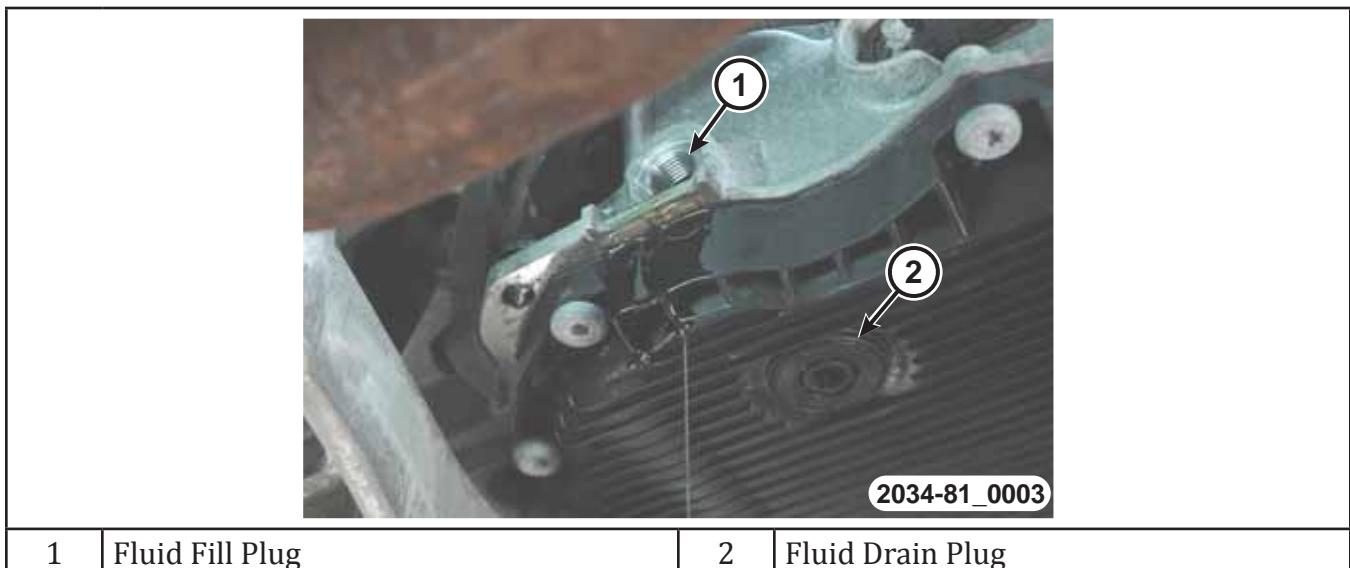

Figure 11 Fluid Level Check

A fluid fill tube and indicator are not provided on this transmission. The oil level is only checked or adjusted when the customer has shift quality concerns, fluid leaks are present, or transmission service is required. The procedure involves the use of a scan tool to monitor transmission fluid temperature. Because a fluid fill tube and indicator are not provided, all work is performed under the vehicle while raised on a hoist.

8-Speed Overview and Light Maintenance

Oil Cooler and Temperature Bypass Valve

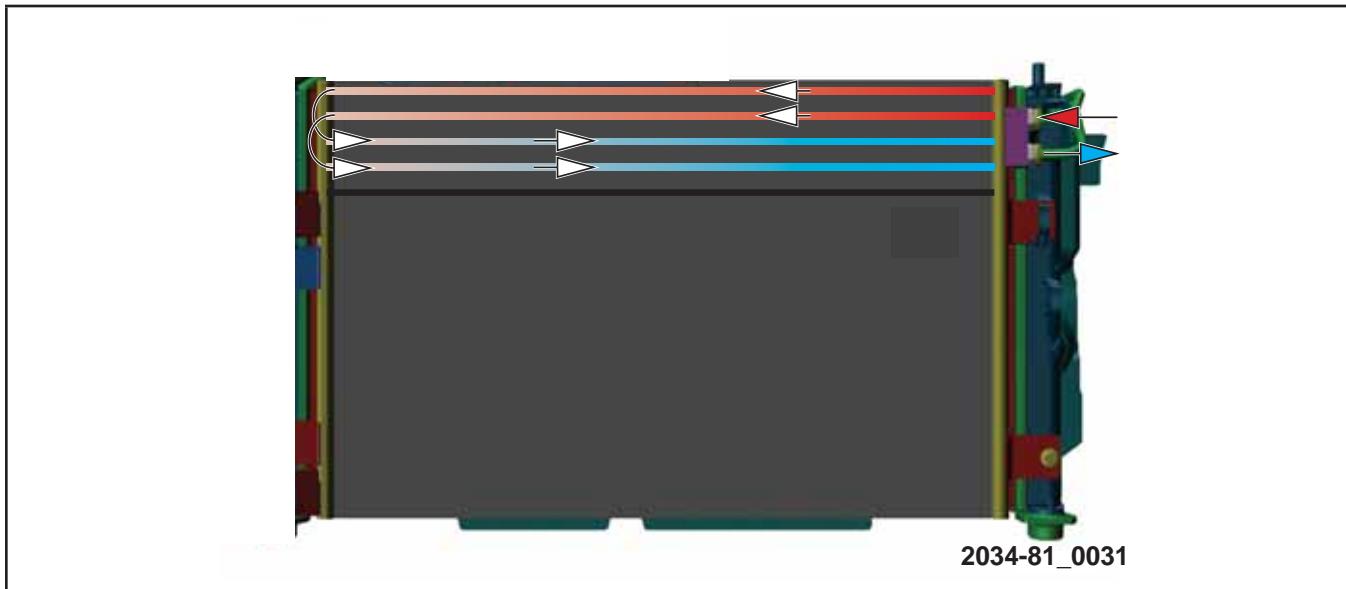

Figure 12 Transmission Cooler and Bypass Valve

The 8-speed automatic transmission uses a combination double pass oil-to-air cooler located in the top of the A/C condenser.

The bypass valve operates based on temperature and pressure to bypass the cooler and direct fluid back to the transmission lubrication circuit.

The bypass valve directs fluid back to the transmission lubrication circuit until the fluid temperature reaches 90 °C (194 °F). When the fluid temperature reaches this threshold, the bypass valve opens and allows fluid to flow through the cooler, then return to the transmission.

In the event of a plugged or restricted cooler, the bypass valve also has the ability to redirect fluid back to the transmission lubrication circuit when the cooler circuit pressure exceeds 482.6 kPa (70 psi).

Transmission Heater

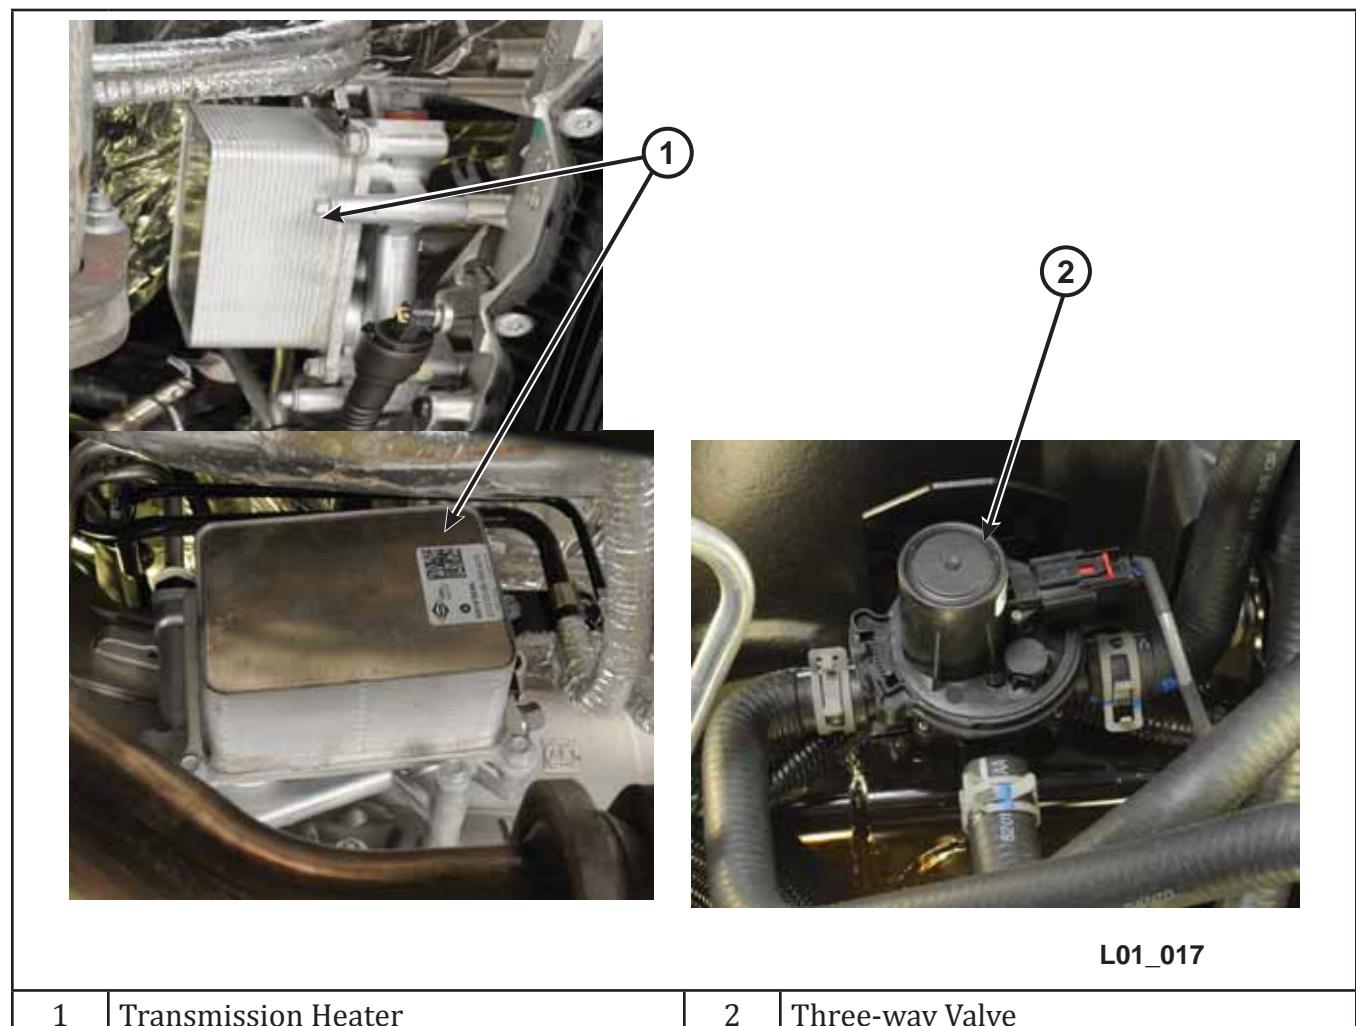

Figure 13 Transmission Heater

Some vehicles may be equipped with a transmission heater. If equipped, the transmission heater is located on the left side of the transmission. The transmission heater is an assembly containing an oil-to-water heat exchanger and also incorporates a thermal bypass valve (TBV). The coolant travels from a three-way valve to the transmission heater. The heated coolant quickly warms the transmission fluid to an ideal operating range. The thermal management system then maintains the optimum operating temperature.

INTERNAL COMPONENTS AND SUB-ASSEMBLIES

Torque Converter

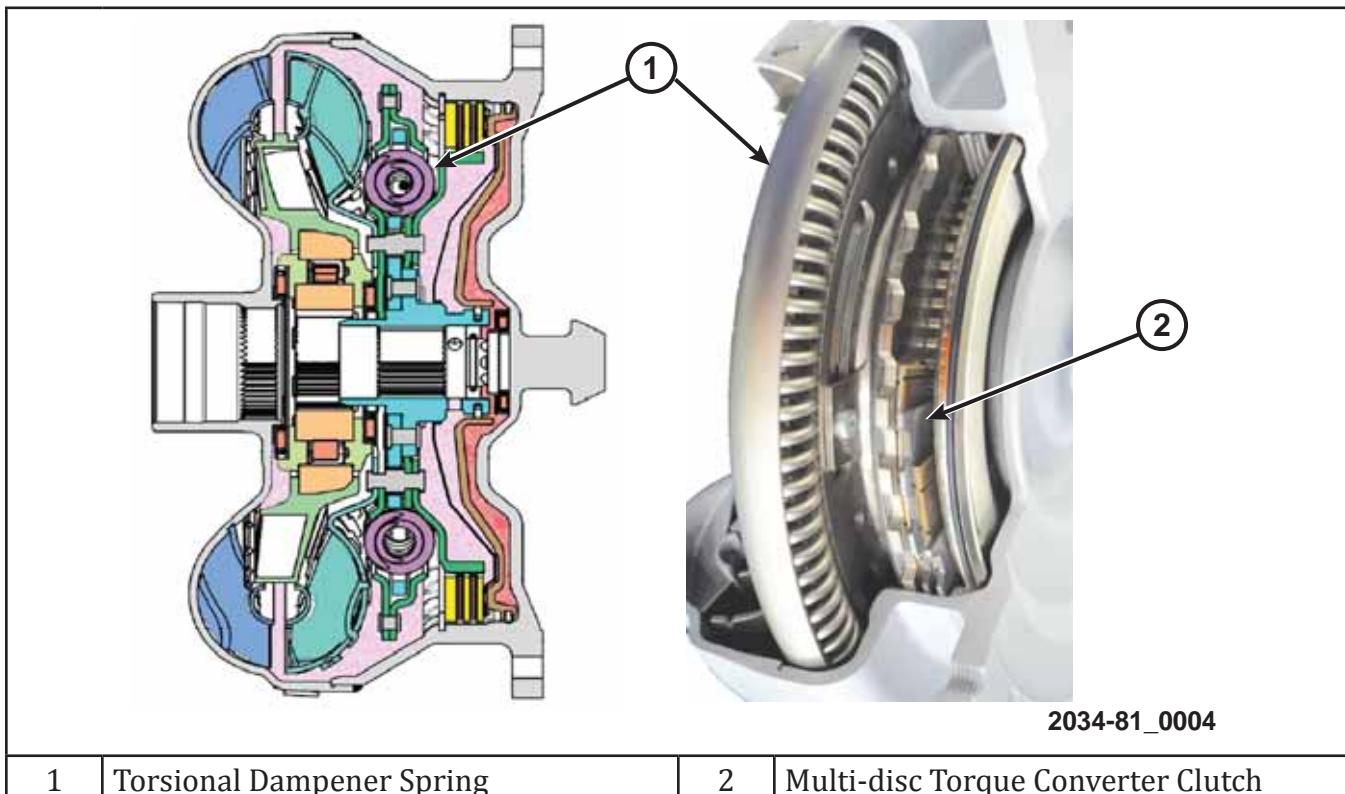

Figure 14 Torque Converter

The 8-speed automatic transmission has a unique housing shape to incorporate the multi-disc torque converter clutch (TCC).

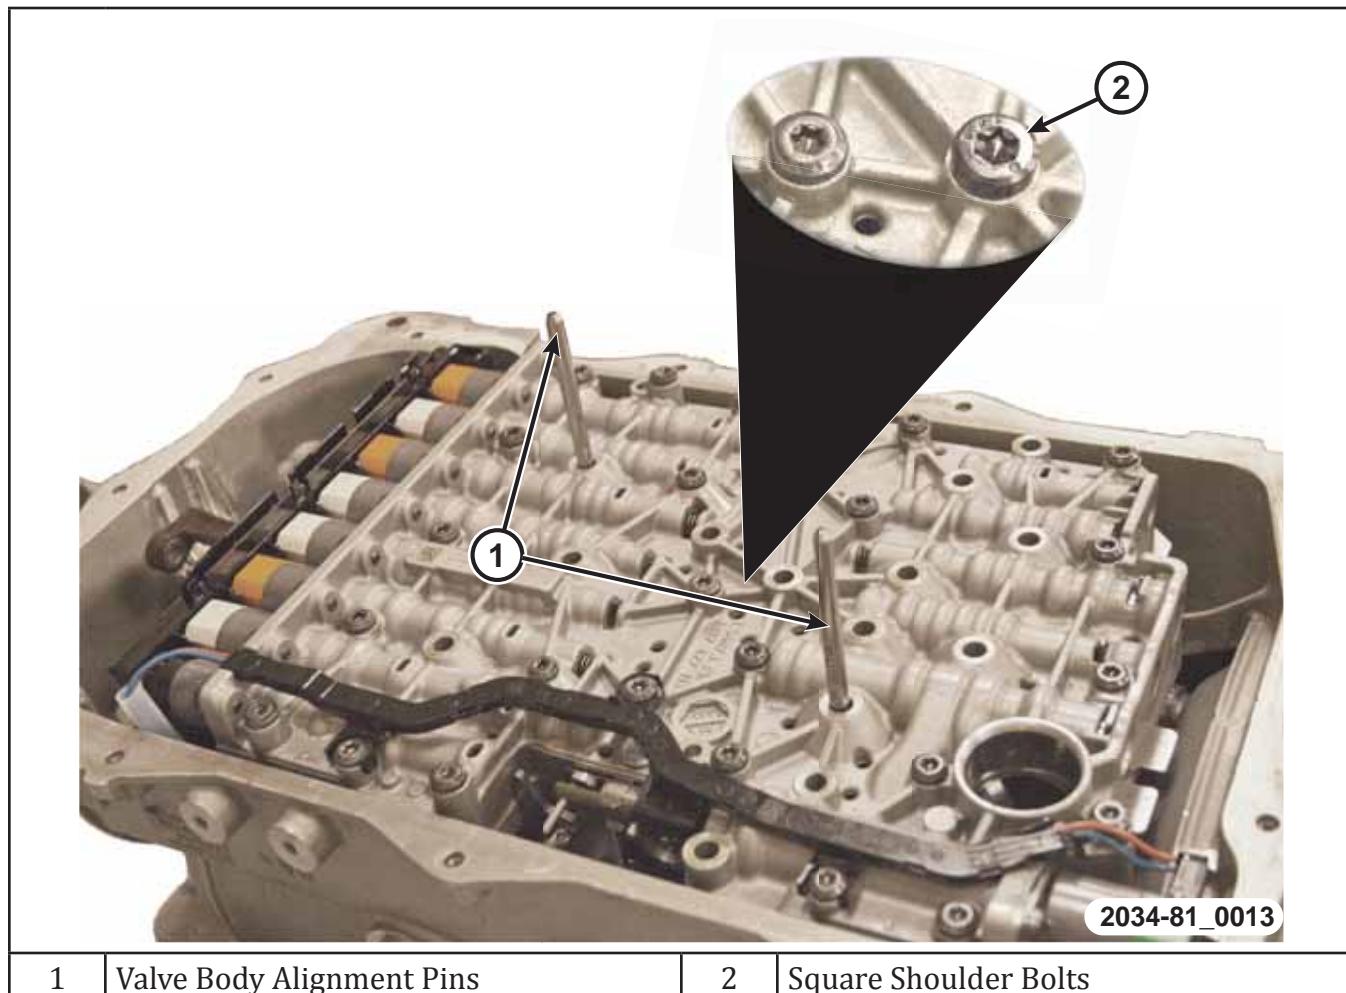

A multi-disc torque converter clutch system improves durability and the holding pressure in the lock-up circuit.

The TCC is allowed to engage in any of the eight forward gears.

A turbine dampening system suppresses torsional vibrations from the engine to ensure optimal shift quality and reduce noise, vibration, and harshness (NVH) concerns.

Valve Body Alignment Pins

1 Valve Body Alignment Pins

2 Square Shoulder Bolts

Figure 15 Valve Body Alignment Pins

The valve body alignment pins guide and align the valve body assembly during installation. These alignment pins are especially useful when installing the valve body assembly while the transmission is still in the vehicle. When the alignment pins are in place, the valve body assembly slides over the pins and aligns to the bolt holes. The alignment pins allow one hand to hold the valve body in place while starting the mounting bolts with the other hand.

Only the square shoulder bolts need to be taken out to remove the valve body.

Electrical Harness Insulator

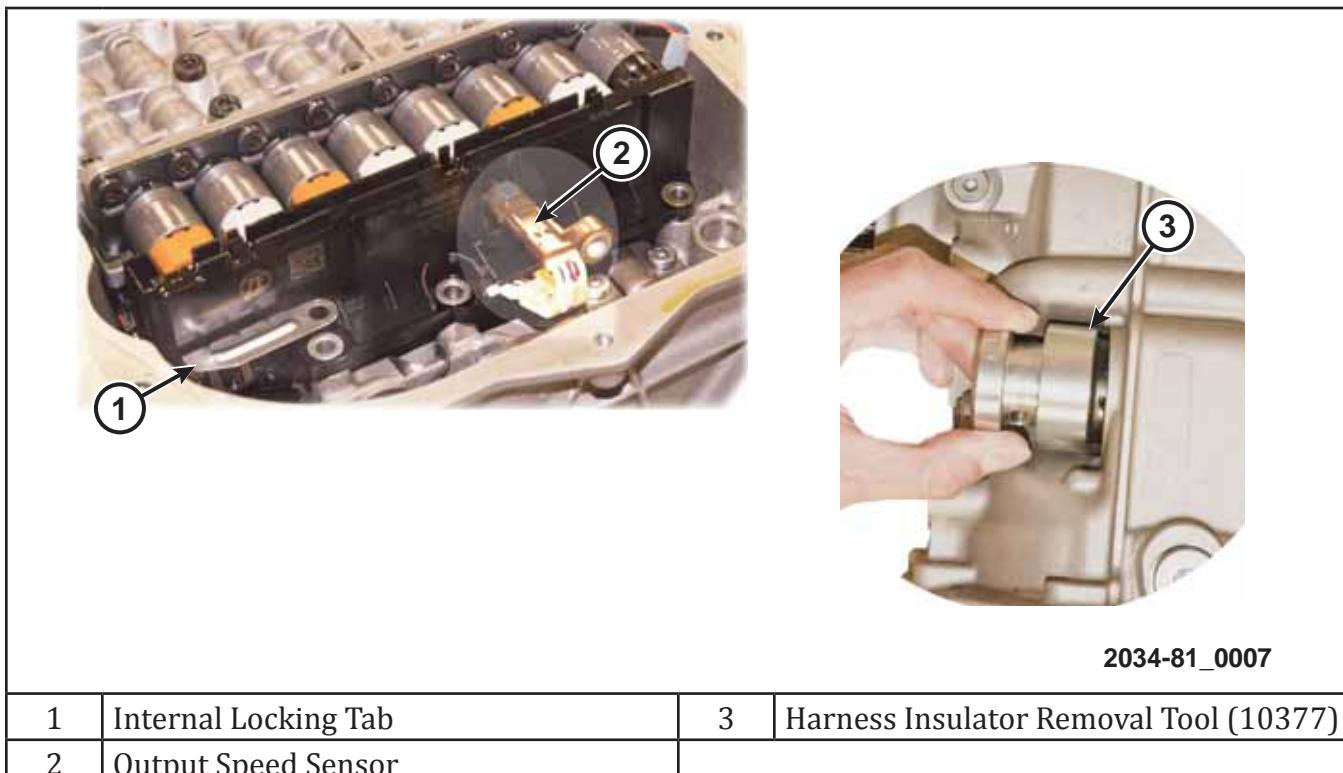

Figure 16 Electrical Harness Insulator

The electrical harness insulator must be removed from the outside of the case before removing the valve body. A special tool has been developed to pull the insulator out after the internal locking tab has been released. This tool works well with the in-vehicle valve body removal procedure.

To help protect the output speed sensor during valve body removal, the sensor is pulled out and folded back so that the tip of the sensor slides into a slot in the center of the molded plastic solenoid frame.

8-Speed Hydro-Mechanical Systems Operation

TCMA Sensors

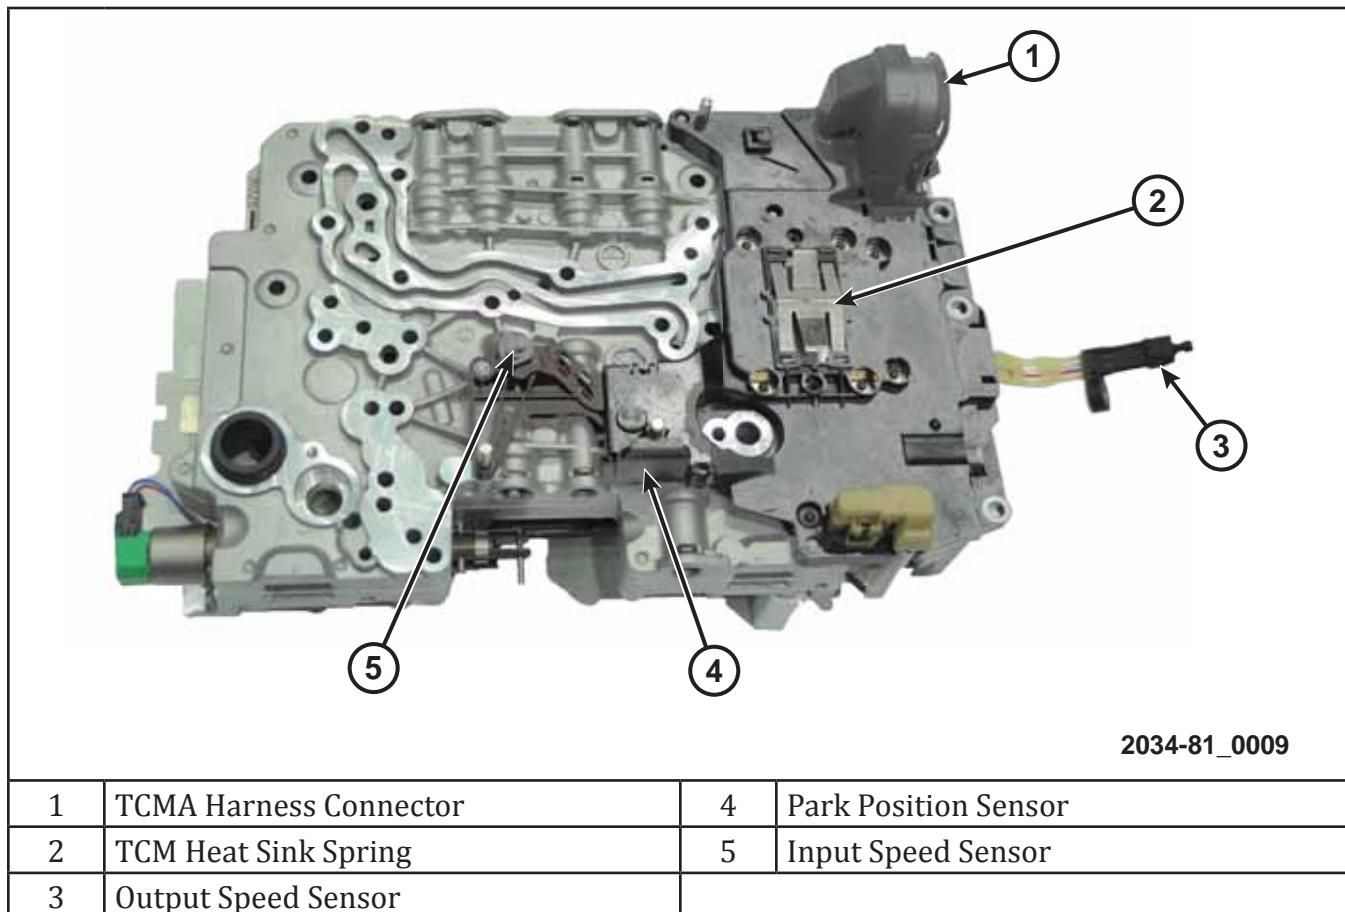

Figure 17 TCMA Sensors

The TCMA includes four transmission sensors that are hard-wired to the TCM. The input and output speed sensors are Hall-effect sensors. The transmission oil temperature sensor is a thermistor. The park position sensor is a three-wire, digital sensor that reports the position of the park lock mechanism.

The TCM uses a heat sink to dissipate heat from the TCM to the transmission case. The heat sink acts like a spring and causes the valve body to pop up when installing.

CAUTION: The TCM can be damaged by electrostatic discharge (ESD). Always take precautions to avoid ESD when handling a valve body assembly. A wrist band grounding device is the most reliable method of diverting electrostatic discharge.

2	Pump Cover Bolt	5	Torque Converter Hub Seal
3	Pump Cover Bolt Seal		

Figure 18 Oil Pump Cover

There are several leak points at the front of the transmission in the converter bellhousing area. Because components in this area are concealed and not visible without transmission removal, it can be difficult to diagnose the leaks that appear at the bottom of the bellhousing. Leaks in this area require transmission and torque converter removal. The converter hub seal, the oil pump cover O-ring, and the bolts are possible leak points at the front of the transmission.

NOTE: The oil pump cover bolts are made of lightweight aluminum alloy. These bolts **MUST** be replaced each time they are removed.

Oil Pump Housing Assembly

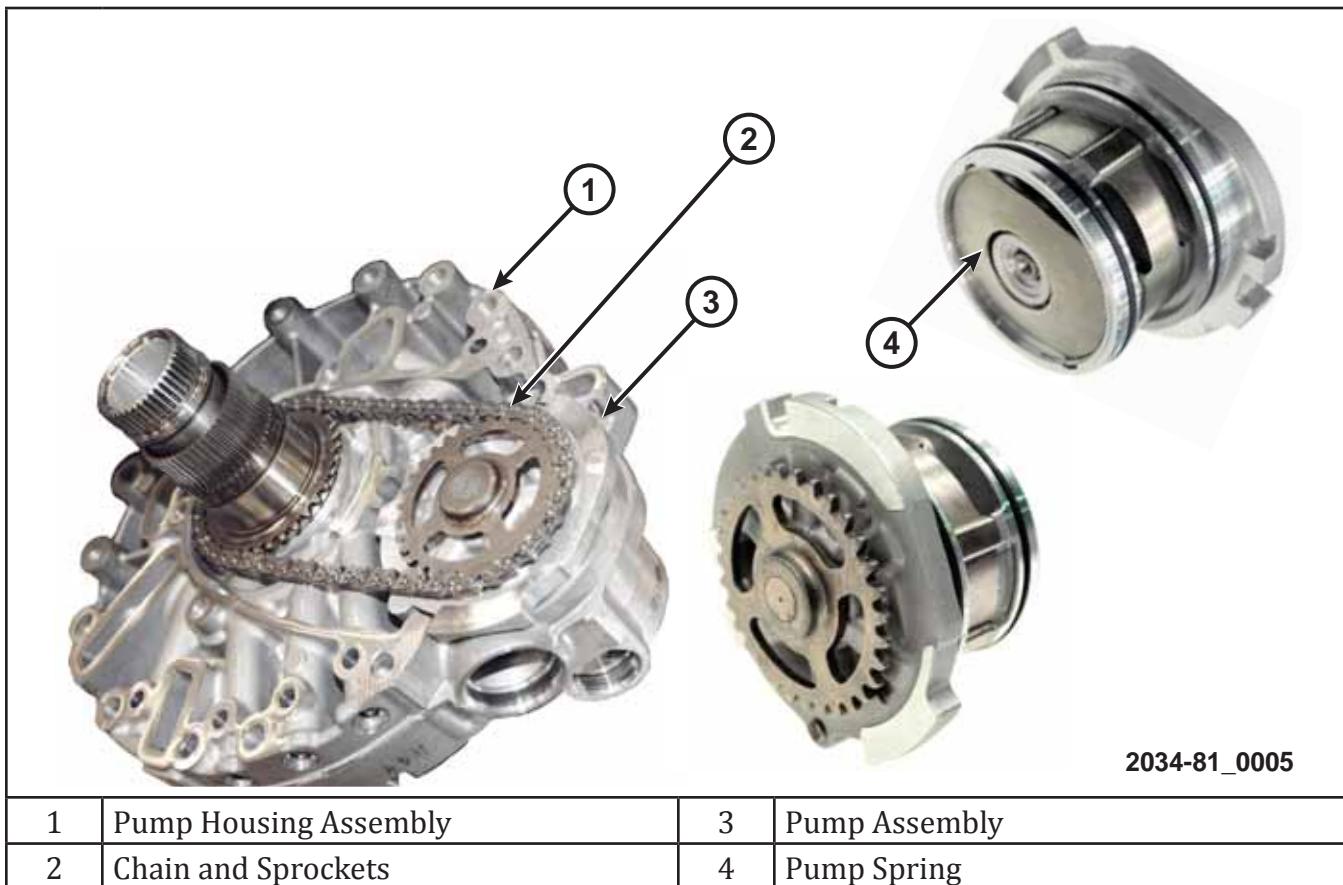

Figure 19 Pump Housing Assembly

The oil pump is located just behind the torque converter, between the pump housing and cover assemblies. The torque converter drives the pump assembly using a chain and sprockets. The oil pump is a double-stroke vane pump. The pump has two inlet ports, two pumping chambers, and two outlet ports, allowing it to produce the fluid volume necessary for all operating conditions.

Geartrain Components

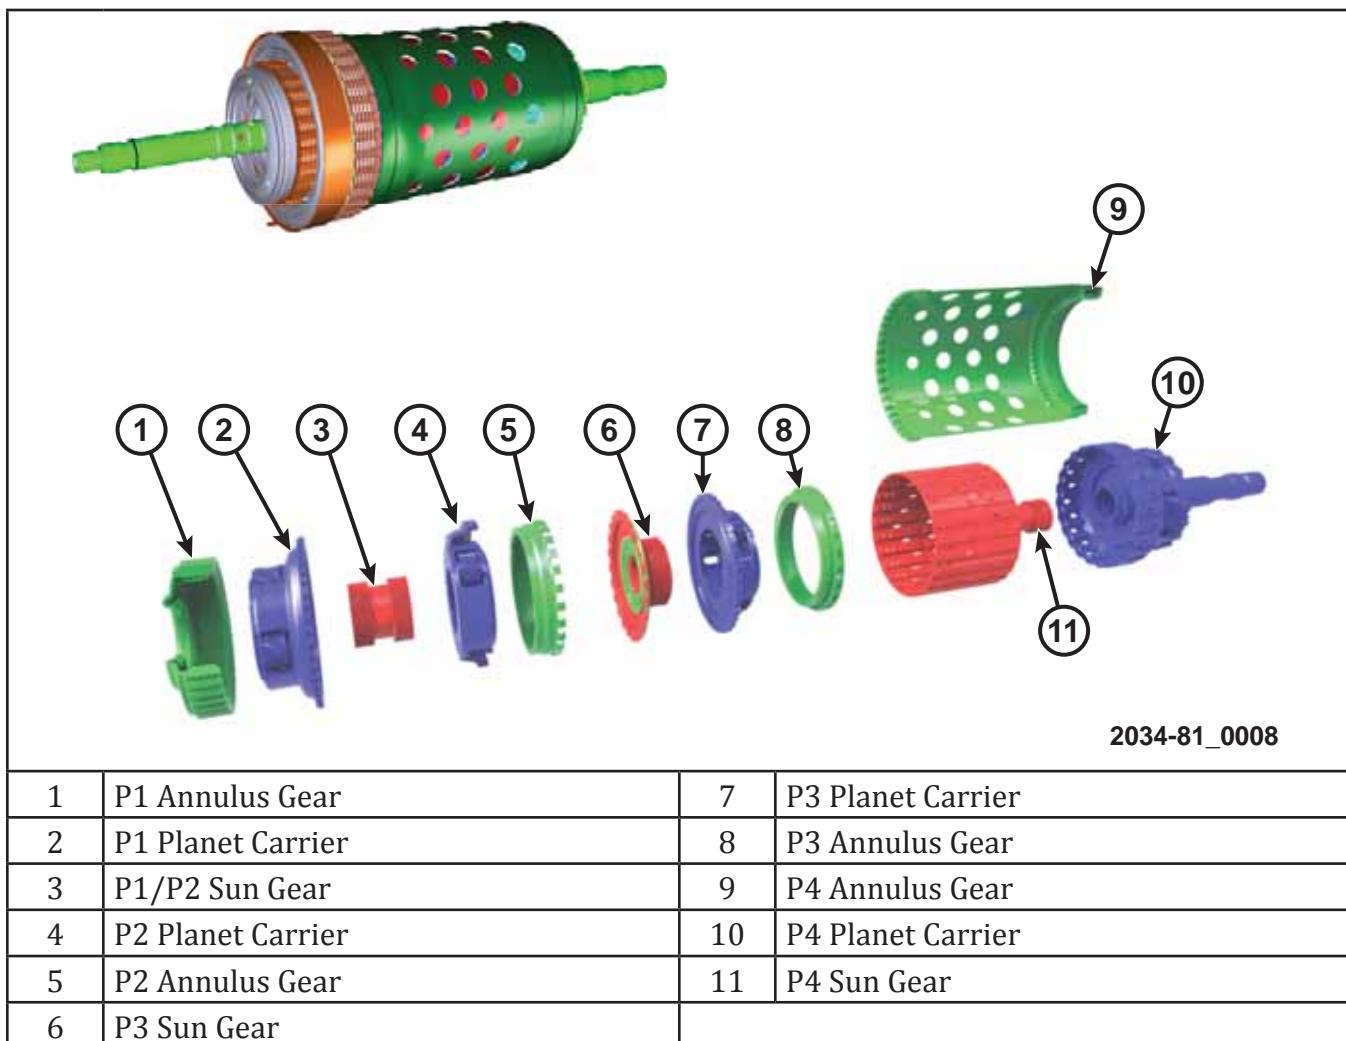

Figure 20 Geartrain Components

The transmission uses four planetary gear sets. The P1 and P2 planetary sets share a common sun gear. This is typically classified as a Simpson gear set. The P3 planetary is a simple planetary gear set and is the third planetary in line. The P4 is another simple planetary gear set and the carrier is part of the output shaft. The P4 carrier is always the final output member in all ranges.

8-Speed Hydro-Mechanical Systems Operation

P4 Annulus Drum Snap Ring

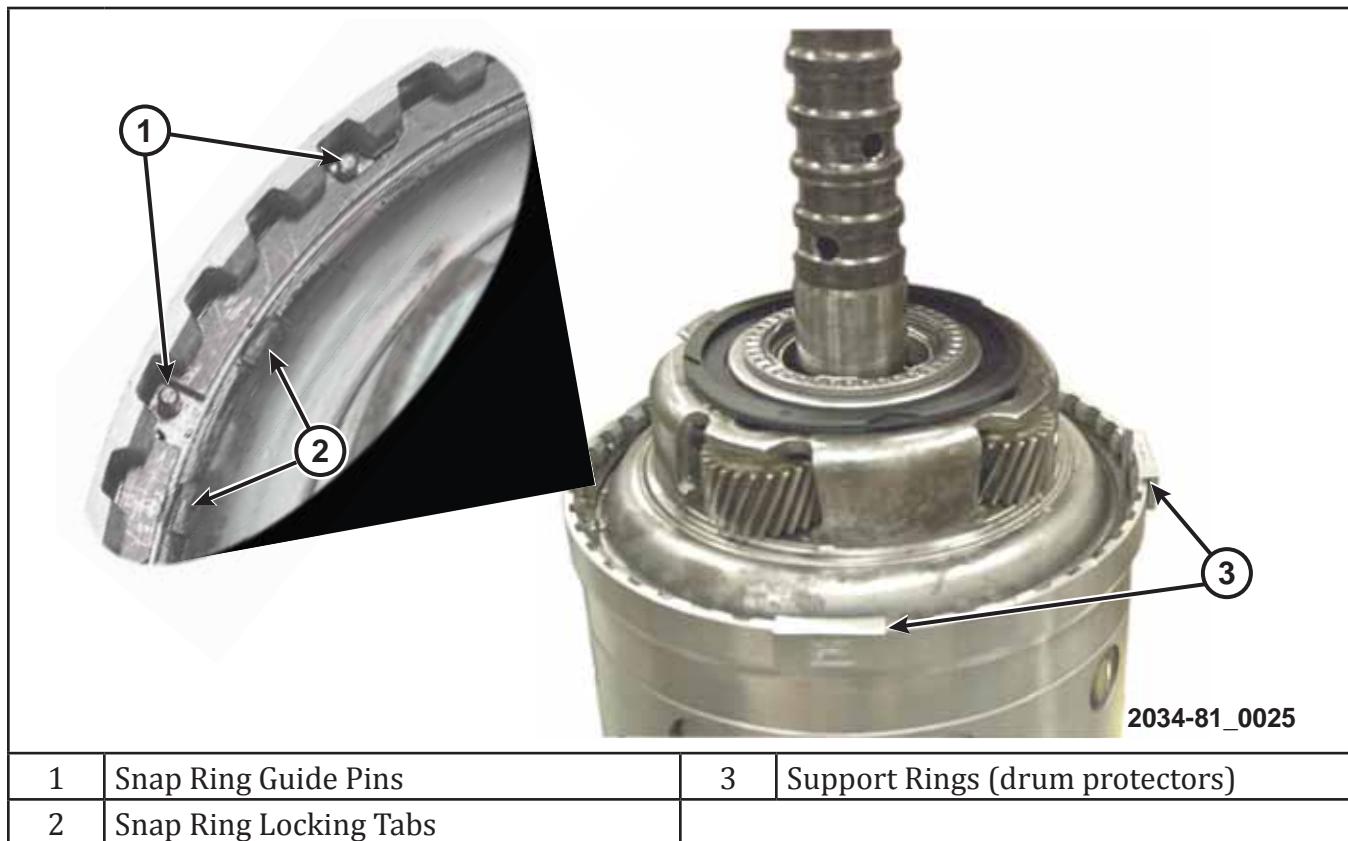

Figure 21 P4 Annulus Drum and Snap Rings

Removing the snap rings within the geartrain assembly requires the use of special support ring tools. Because the aluminum drums rotate at extremely high speeds in the upper gear ranges, the drums are precisely balanced to eliminate vibration. When removing the snap rings, the support rings protect the edge of the drums and snap ring grooves from nicks that remove material from the drum.

NOTE: The snap rings must be replaced whenever they are removed.

CAUTION: The aluminum drums must be handled with care. Do not drop or dent the drums during service. Always inspect the drum carefully for excessive loss of metal around the snap ring retainer groove and for deformation.

Clutches

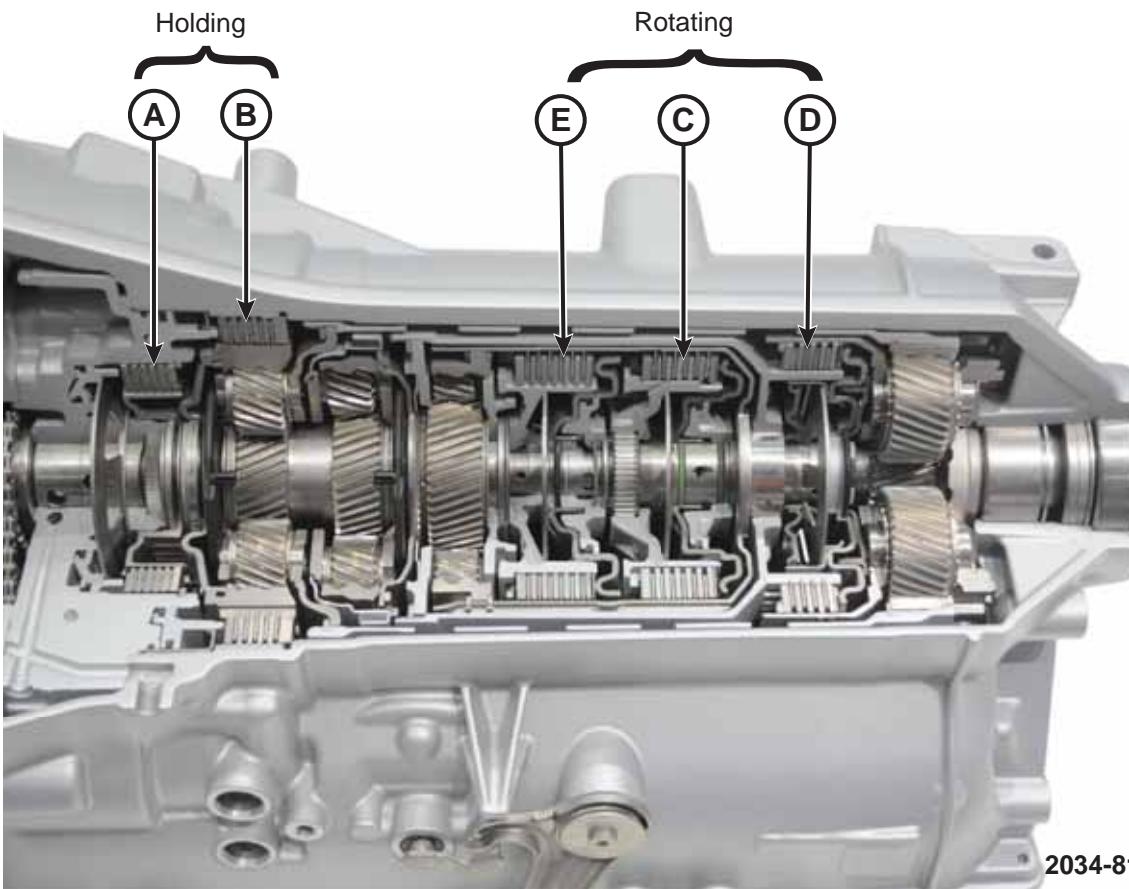

Figure 22 Clutches

This transmission uses five multi-disc clutch packs to control the power flow through the four planetary gear sets. Combinations of any three clutches are applied in each gear range.

- The A and B clutches are holding clutches.
- The B clutch has two hydraulic chambers, one on each side of the apply piston; clutch release is controlled by hydraulic pressure and not a return spring.
- The E, C, and D clutches are driving or rotating clutches.

The 8HP45 transmission achieves eight forward gear ranges and reverse by using four planetary gear sets and five multi-disc clutches. The gear sets are identified as P1, P2, P3, and P4. Clutches are identified as clutch A, B, E, C, and D (from the front of the transmission to the rear). The P1/P2 sun gear is a one-piece gear with teeth on each end.

Holding Clutches

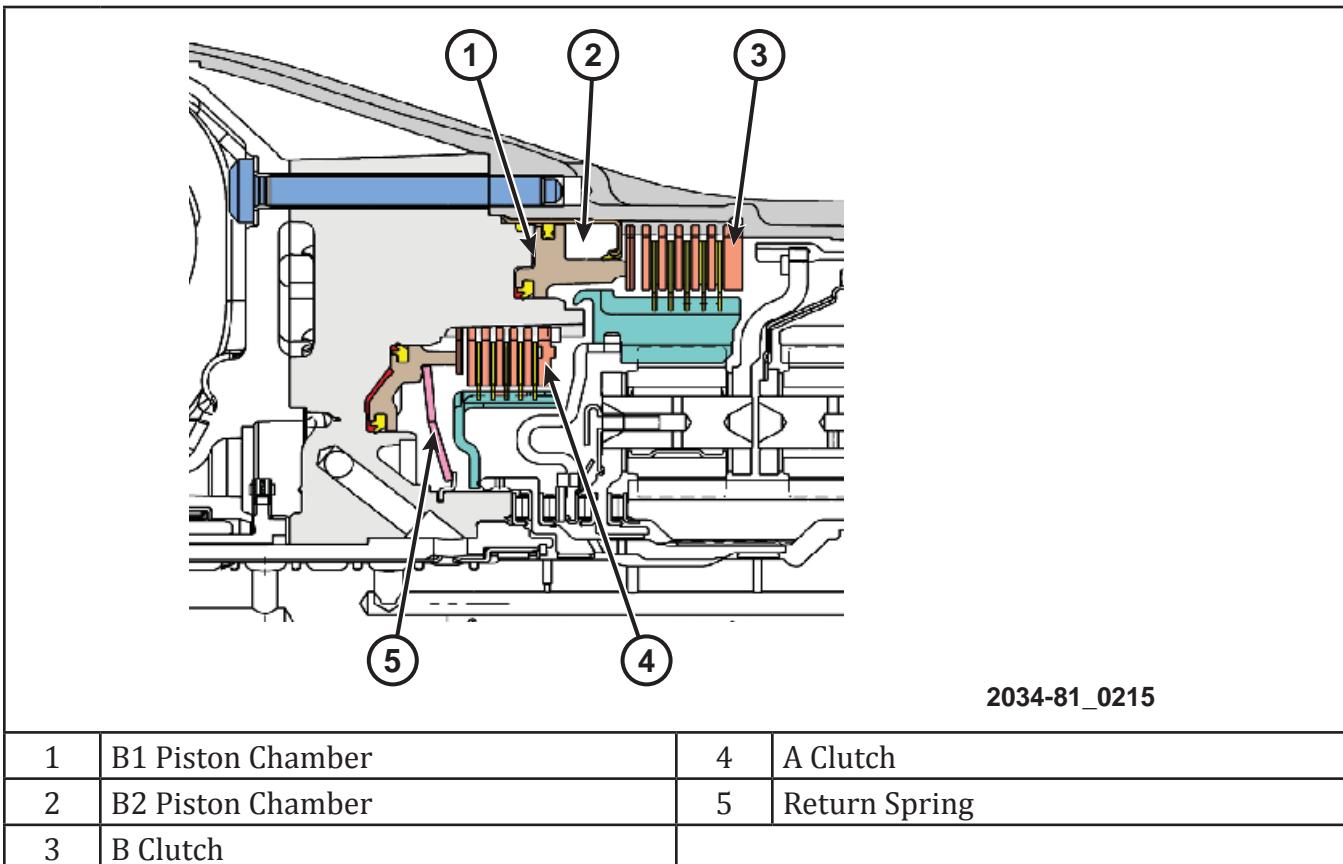

Figure 25 Holding Clutches

The 8HP45 transmission uses two multi-disc holding clutches (A and B). Every gear shift on the 8HP45 is a synchronous shift: one of the clutches must continue to transmit the torque at lower pressure until the other clutch is able to accept the input torque.

- The A clutch is splined to the P1/P2 sun gear.
- The B clutch is splined to the P1 annulus gear.

8-Speed Hydro-Mechanical Systems Operation

Rotating Clutches

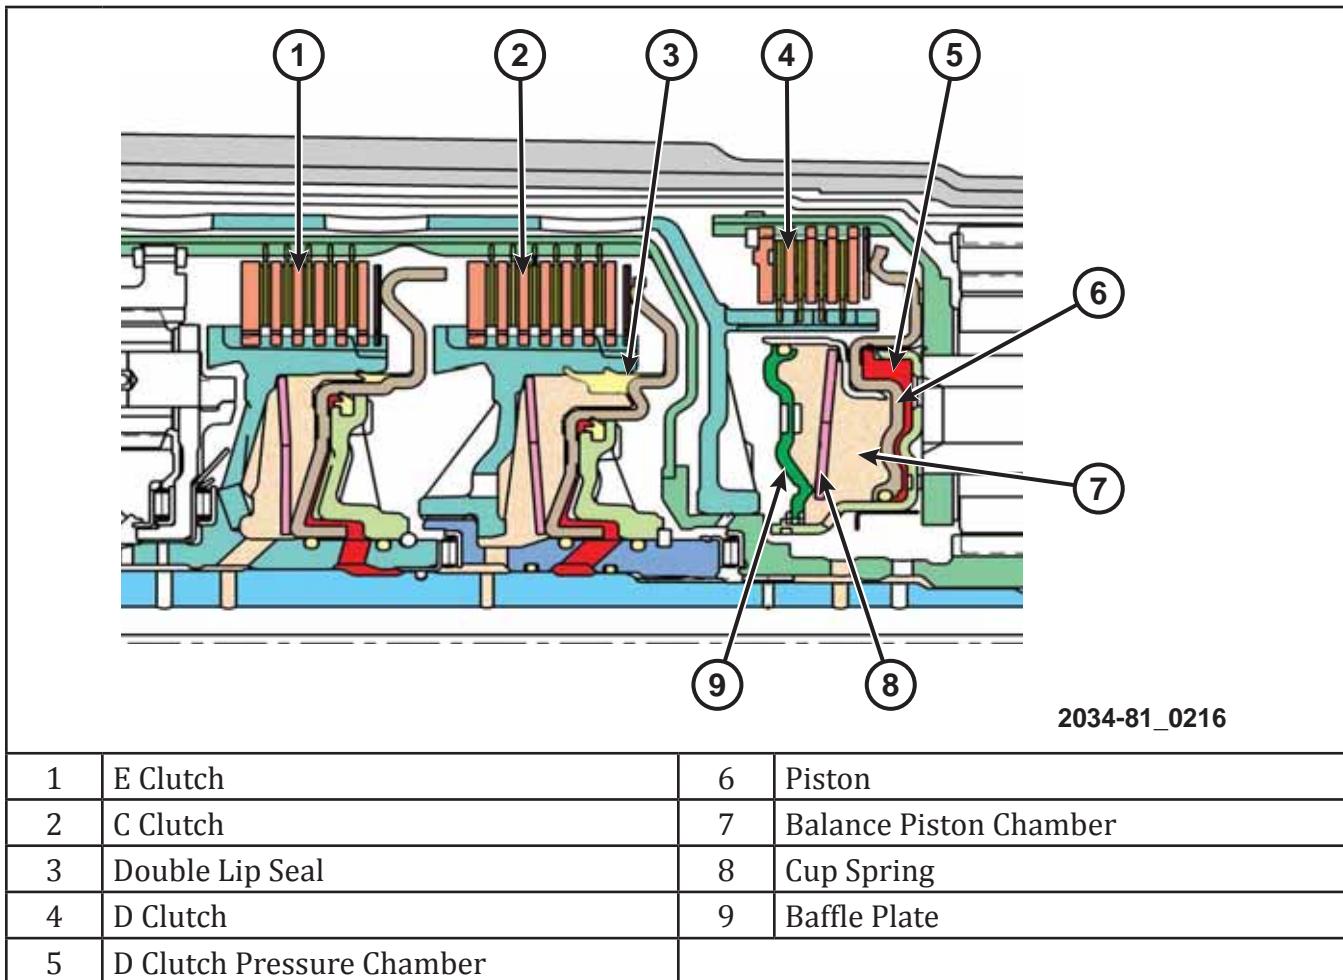

Figure 26 Rotating Clutches

Rotating clutches E, C, and D supply power from the engine to the planetary gear train. All clutches are engaged hydraulically. All rotating clutches use a balance piston to keep the clutch from dragging when released.

1st Gear

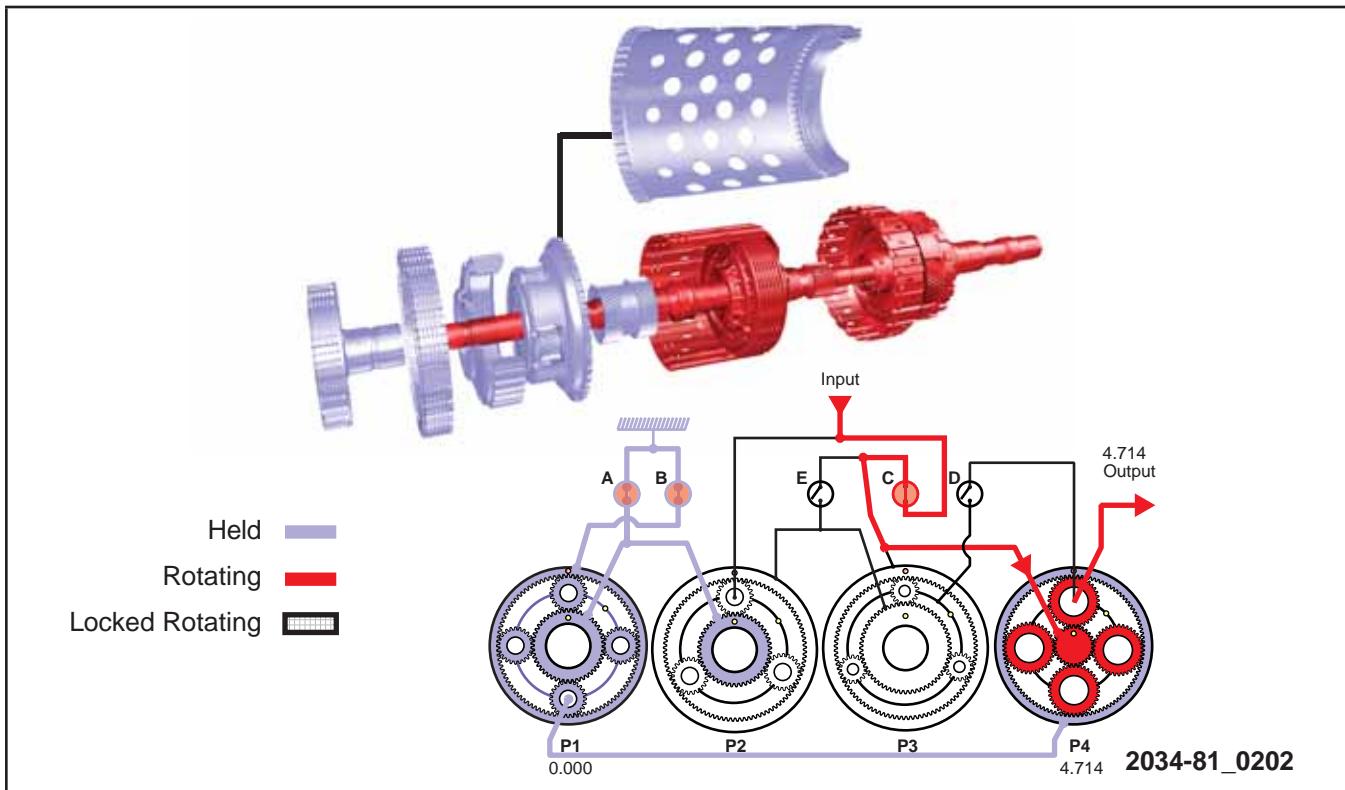

Figure 27 1st Gear

In 1st gear, the A clutch holds the P1/P2 sun gear and the B clutch holds the P1 annulus. Because two members of the same gear set are held, the entire P1 gear set is stationary. The stationary P1 carrier is connected to the P4 annulus and holds the annulus.

The input shaft drives the C clutch, and the C clutch drives the P4 sun gear. The P4 sun gear drives the P4 carrier, whose pinions walk around the held P4 annulus.

8-Speed Hydro-Mechanical Systems Operation

2nd Gear

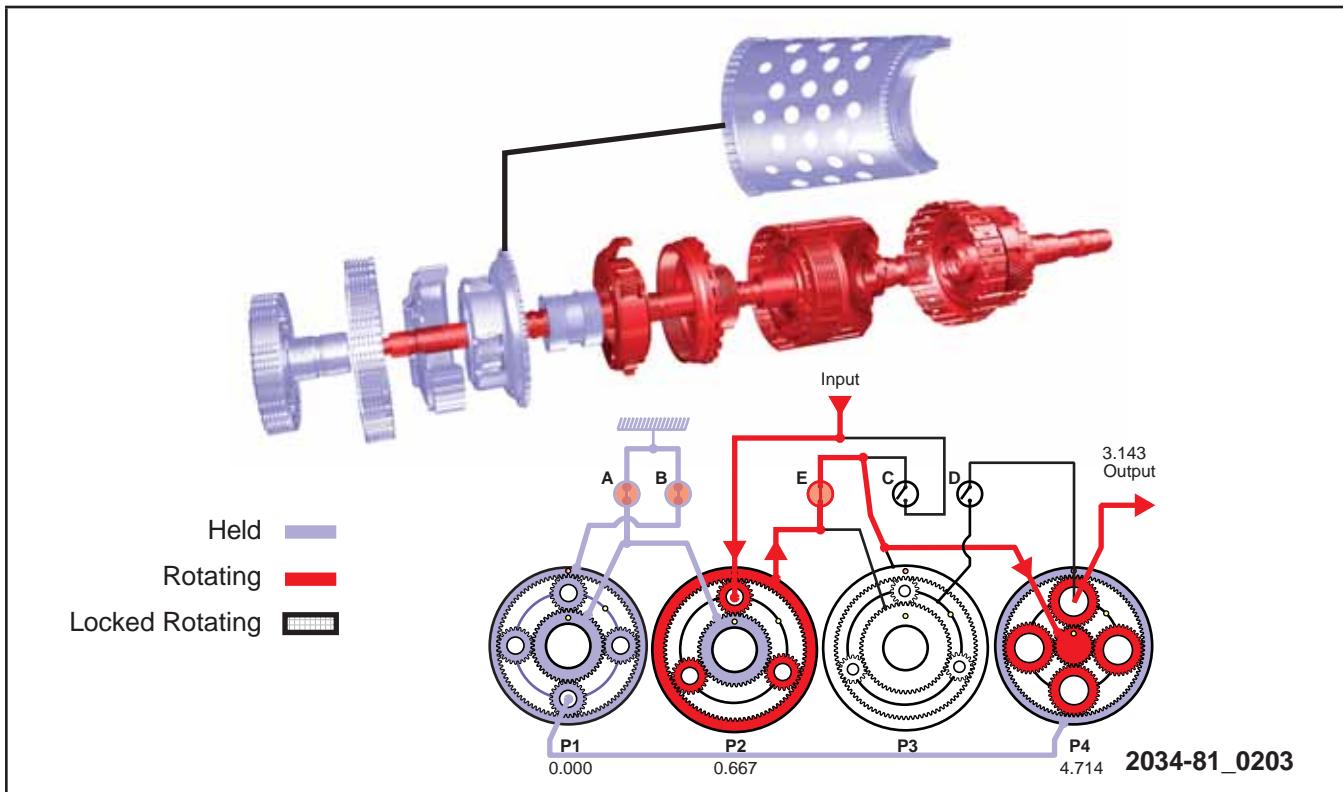

Figure 28 2nd Gear

In 2nd gear, the A clutch holds the P1/P2 sun gear and the B clutch holds the P1 annulus. As with 1st gear, the entire P1 gear set is stationary. The stationary P1 carrier is connected to the P4 annulus and holds the annulus.

The input shaft drives the P2 carrier. The P2 carrier drives the P2 annulus. The P2 annulus drives the E clutch through the P3 sun gear connection. The E clutch then drives the P4 sun gear. The P4 sun gear drives the P4 carrier, whose pinions walk around the held P4 annulus.

3rd Gear

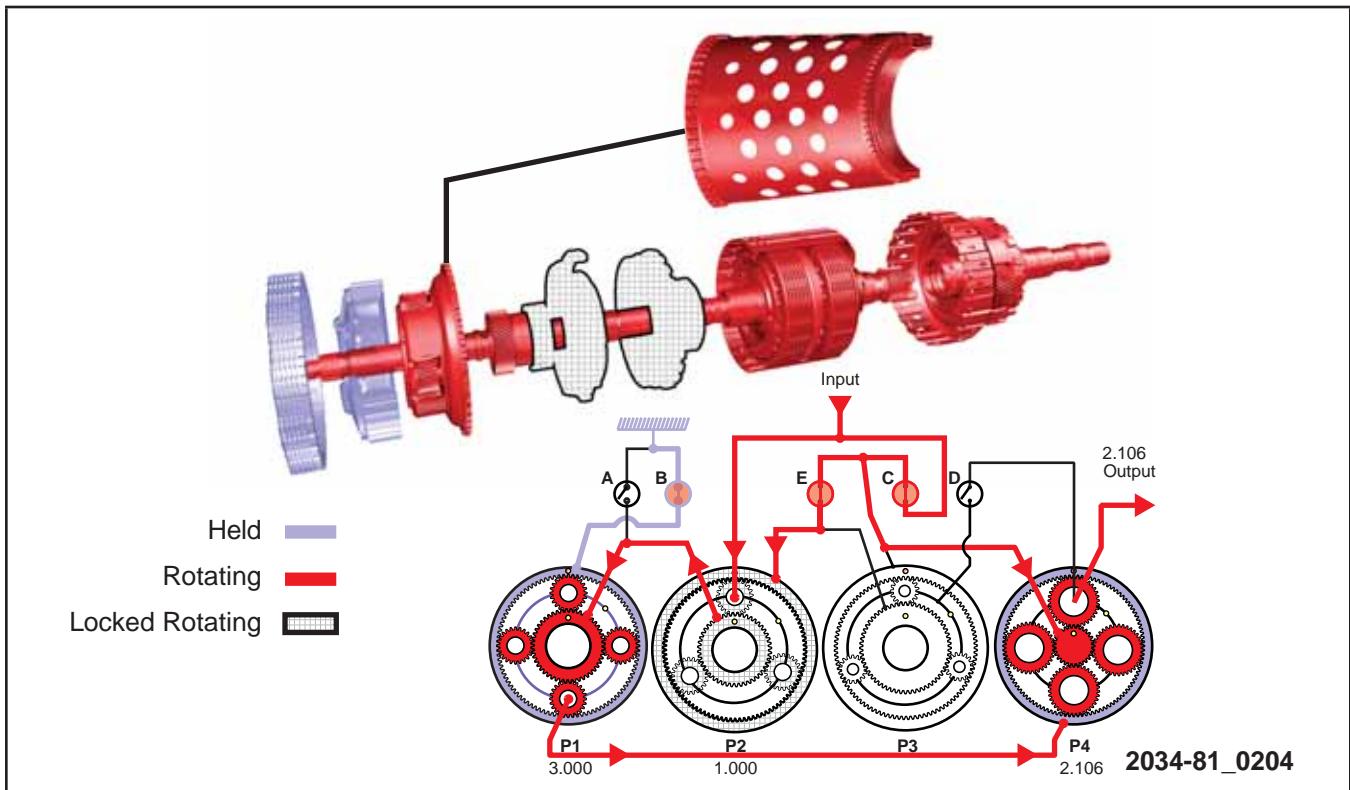

Figure 29 3rd Gear

In 3rd gear, the B clutch holds the P1 annulus.

The input shaft drives the C clutch, which drives the P4 annulus. The C clutch also drives the E clutch, which drives the P2 annulus. Because the P2 carrier and the P2 annulus are both driven at input shaft speed, the P2 gear set is locked at input shaft speed.

The P1/P2 sun gear drives the P1 carrier, and the P1 carrier drives the P4 annulus.

8-Speed Hydro-Mechanical Systems Operation

4th Gear

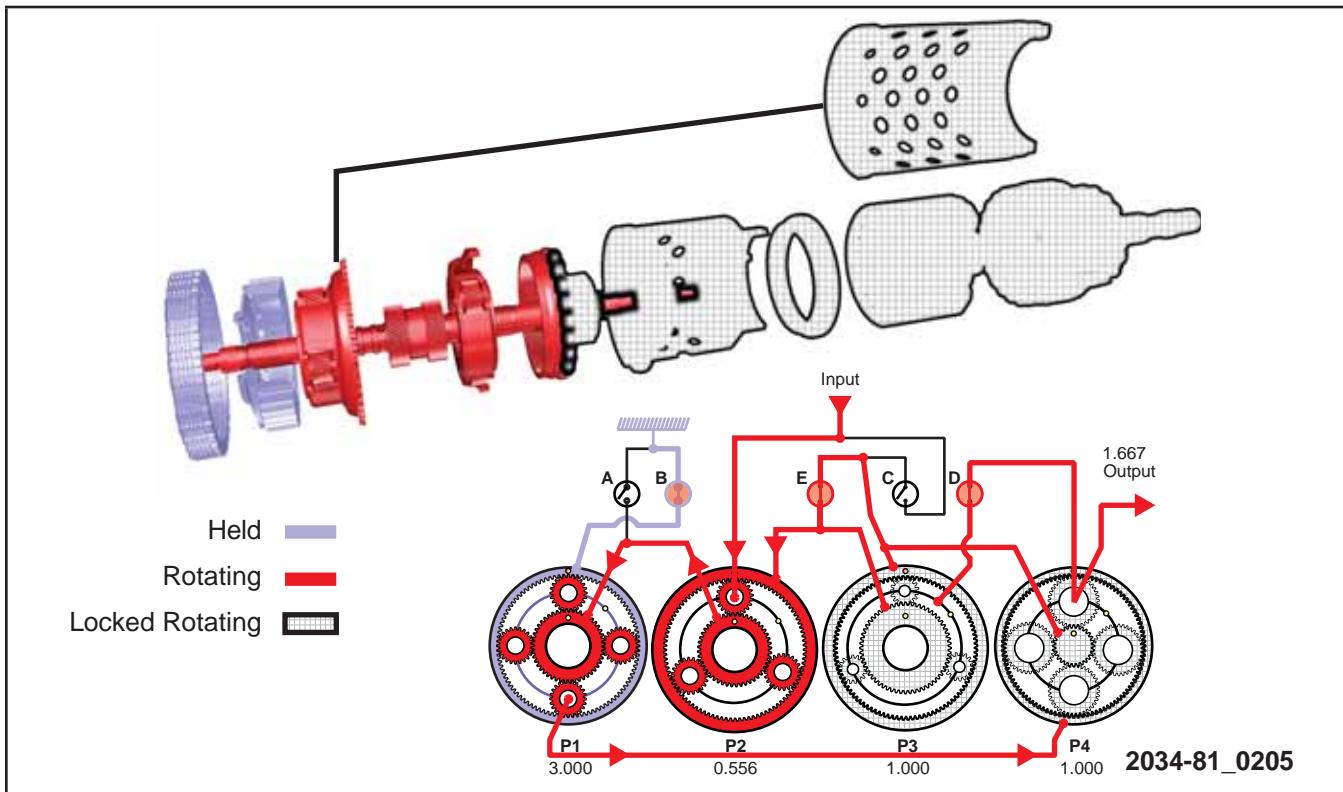

Figure 30 4th Gear

In 4th gear, the B clutch holds the P1 annulus. With the E and D clutches applied, all components of the P3 and P4 gear sets are locked together to rotate at the same speed.

The input shaft drives the P2 carrier, which drives the P1/P2 sun gear. The P1/P2 sun gear drives the P1 carrier. The P1 carrier drives the P4 gear set through the P4 annulus.

5th Gear

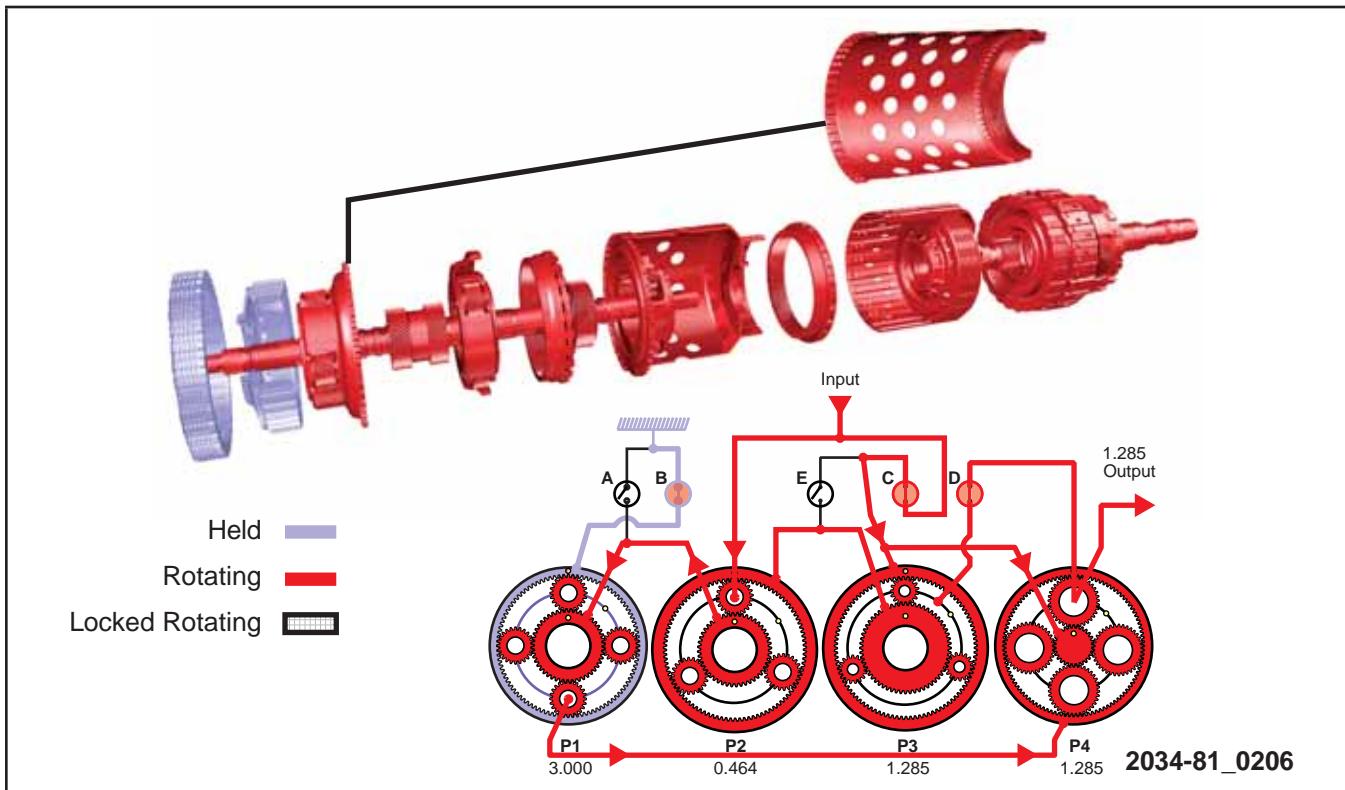

Figure 31 5th Gear

In 5th gear, the B clutch holds the P1 annulus. The input shaft always drives the P2 carrier. Because the C clutch is applied, the P3 annulus and P4 sun gear are also driven at input shaft speed. The D clutch is applied to connect the P3 carrier with the P4 carrier.

The P2 carrier drives the P1/P2 sun gear, which drives the P1 carrier. The P1 carrier walks around the held P1 annulus and drives the P4 annulus. Gear reduction is achieved between the P4 sun gear rotating at input shaft speed and the P4 annulus rotating at a reduced speed.

8-Speed Hydro-Mechanical Systems Operation

6th Gear

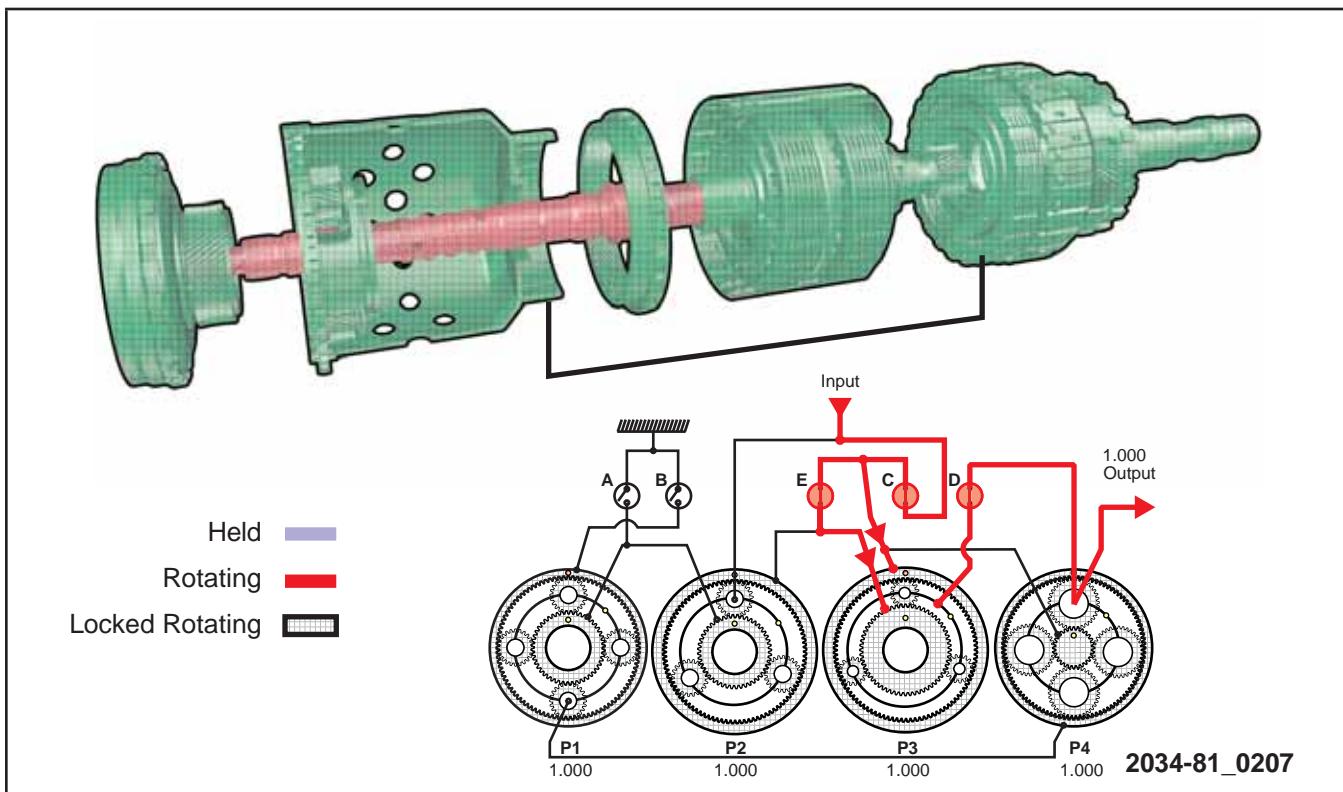

Figure 32 6th Gear

In 6th gear, the C clutch drives the P3 annulus at input shaft speed and the E clutch drives the P3 sun gear at input shaft speed. Because two components of the same gear set are driven at the same speed, the entire gear set is locked in rotation. The D clutch connects the P3 carrier to the P4 carrier and the output shaft.

7th Gear

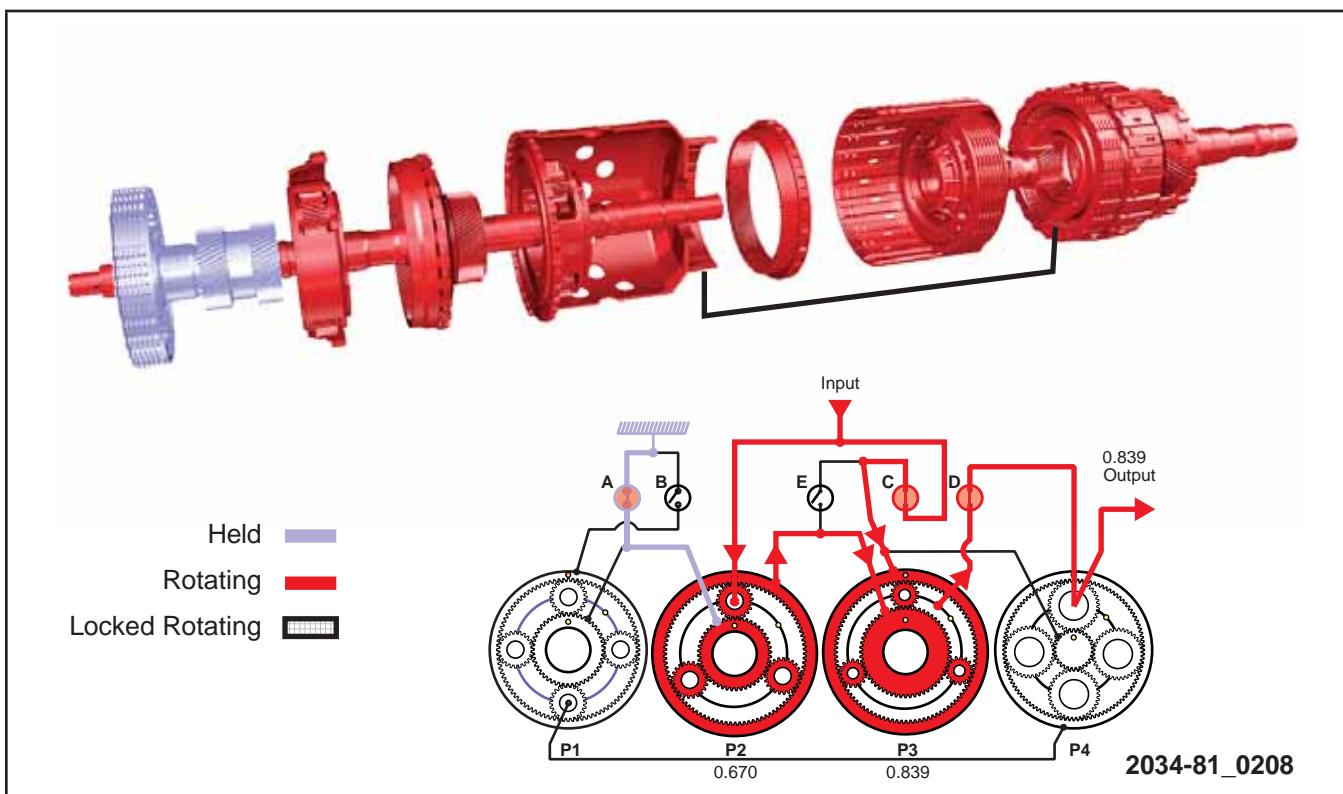

Figure 33 7th Gear

In 7th gear, the A clutch holds the P1/P2 sun gear stationary. The input shaft drives the P2 carrier, which drives the P2 annulus, increasing the speed of the P3 sun gear and creating overdrive.

The C clutch drives the P3 annulus at input shaft speed. The P3 sun gear spins at a faster speed than the P3 annulus, and the P3 carrier is the output of the gear set. This results in a reduction that offsets the overdrive of the P2 gear set.

The D clutch connects the P3 carrier to the P4 carrier and the output shaft.

8-Speed Hydro-Mechanical Systems Operation

8th Gear

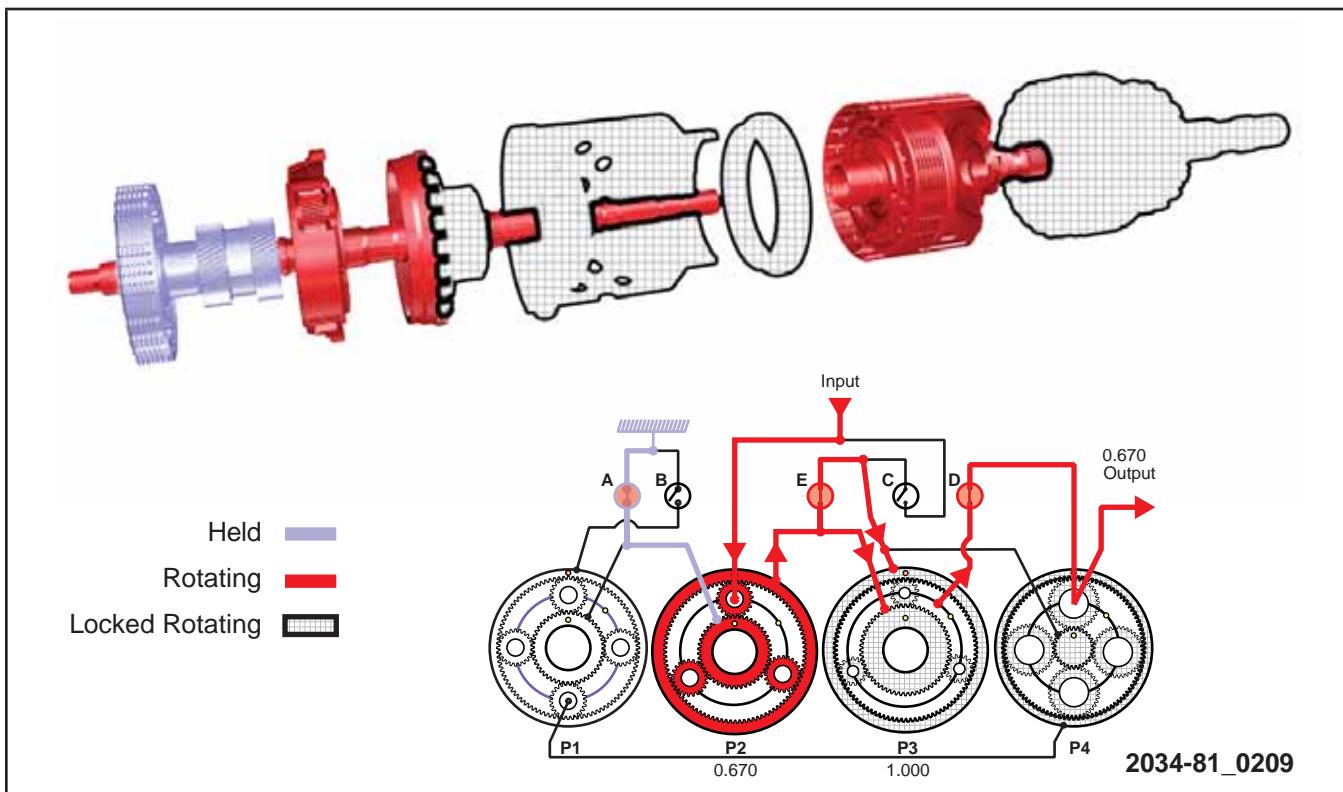

Figure 34 8th Gear

In 8th gear, the A clutch holds the P1/P2 sun gear stationary. As with 7th gear, the P2 gear set creates an overdrive ratio. However, the E clutch applies, which holds the P3 gear set together and eliminates any torque multiplication from the P3 gear set.

The overdrive created by P2 is transferred by the D clutch to the output shaft.

Reverse Gear

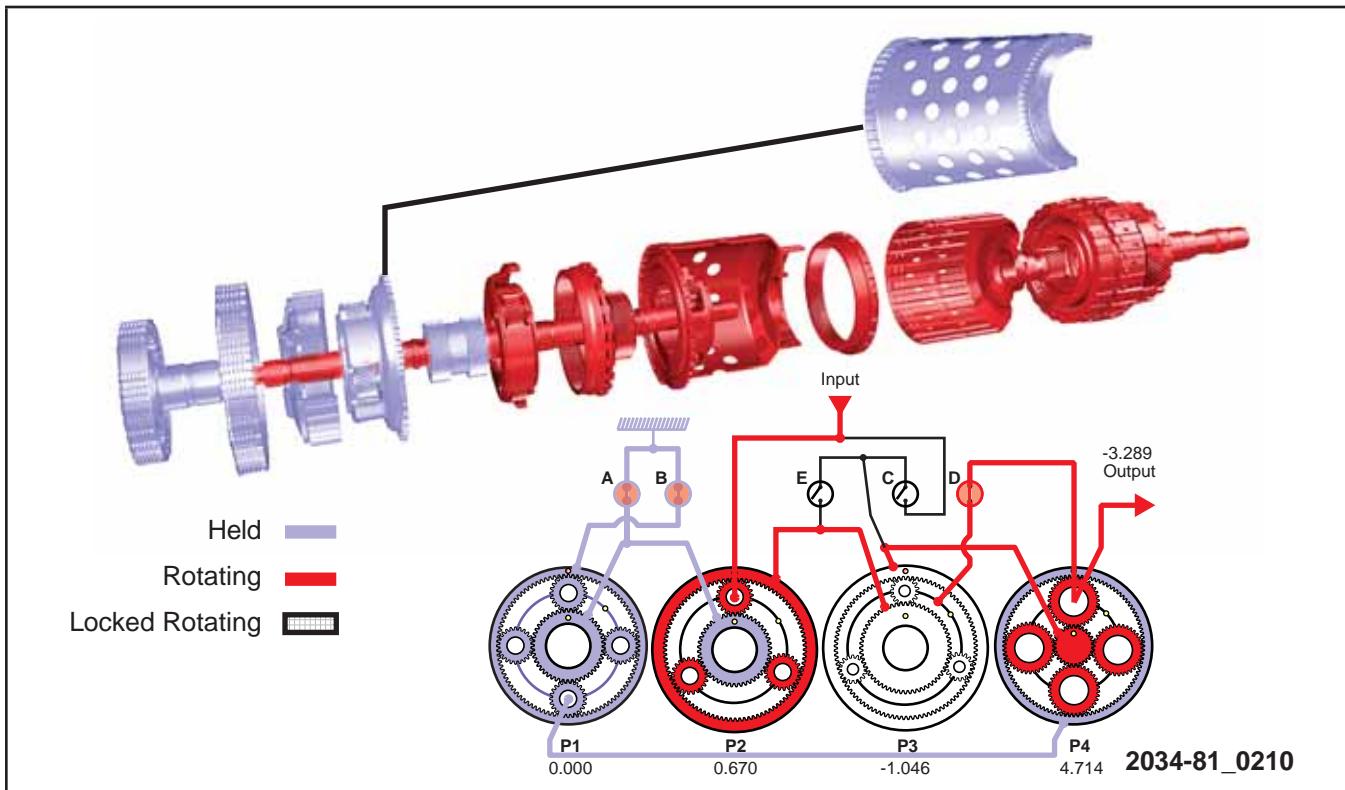

Figure 35 Reverse Gear

In reverse, the A and B clutches apply, holding the P1/P2 sun gear and the P1 annulus gear.

The input shaft drives the P2 carrier, which produces an overdrive ratio from the P2 gear set, driving the P3 sun gear in the same direction as the engine. The P3 carrier is connected to the output shaft by the D clutch. This holds the carrier, reversing the direction and multiplying torque. The P3 annulus is connected to the P4 sun gear, which drives the P4 gear set opposite of engine direction and multiplies torque again.

8-Speed Hydro-Mechanical Systems Operation

Oil Pump Operation

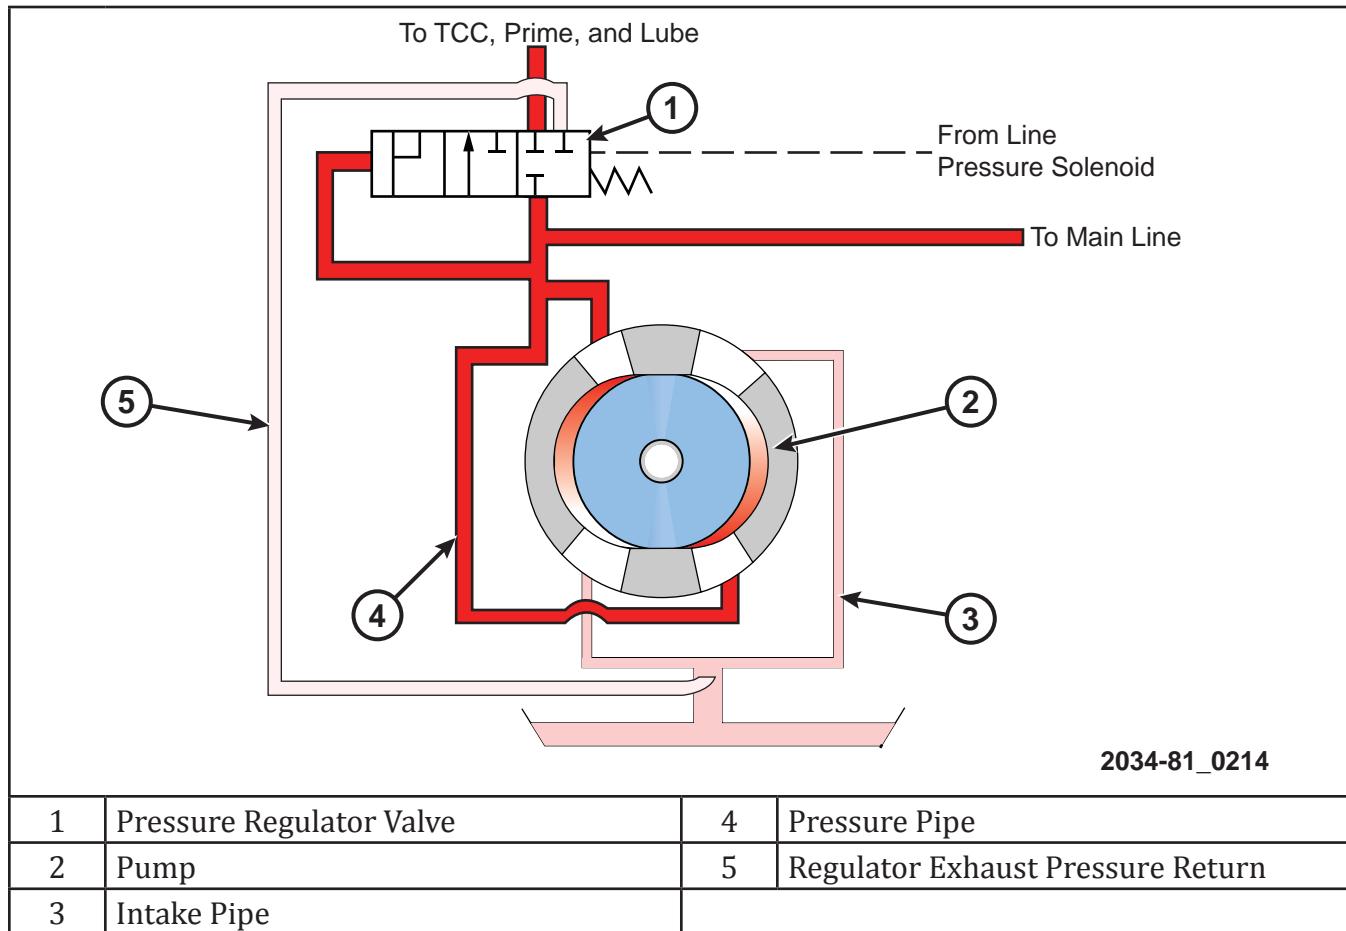

Figure 37 Oil Pump Operation

The transmission oil pump is driven by a chain and sprocket. The oil pump has two intake ports and two exhaust ports. The pump draws fluid through a filter and pressurizes the fluid as the pump rotates. After the fluid is pressurized, it exits the pump through two exhaust ports that feed the system pressure valve. The system pressure valve maintains fluid pressure and allows excess pressure to be returned to the pump. This reduces cavitation and noise.

TCC Release

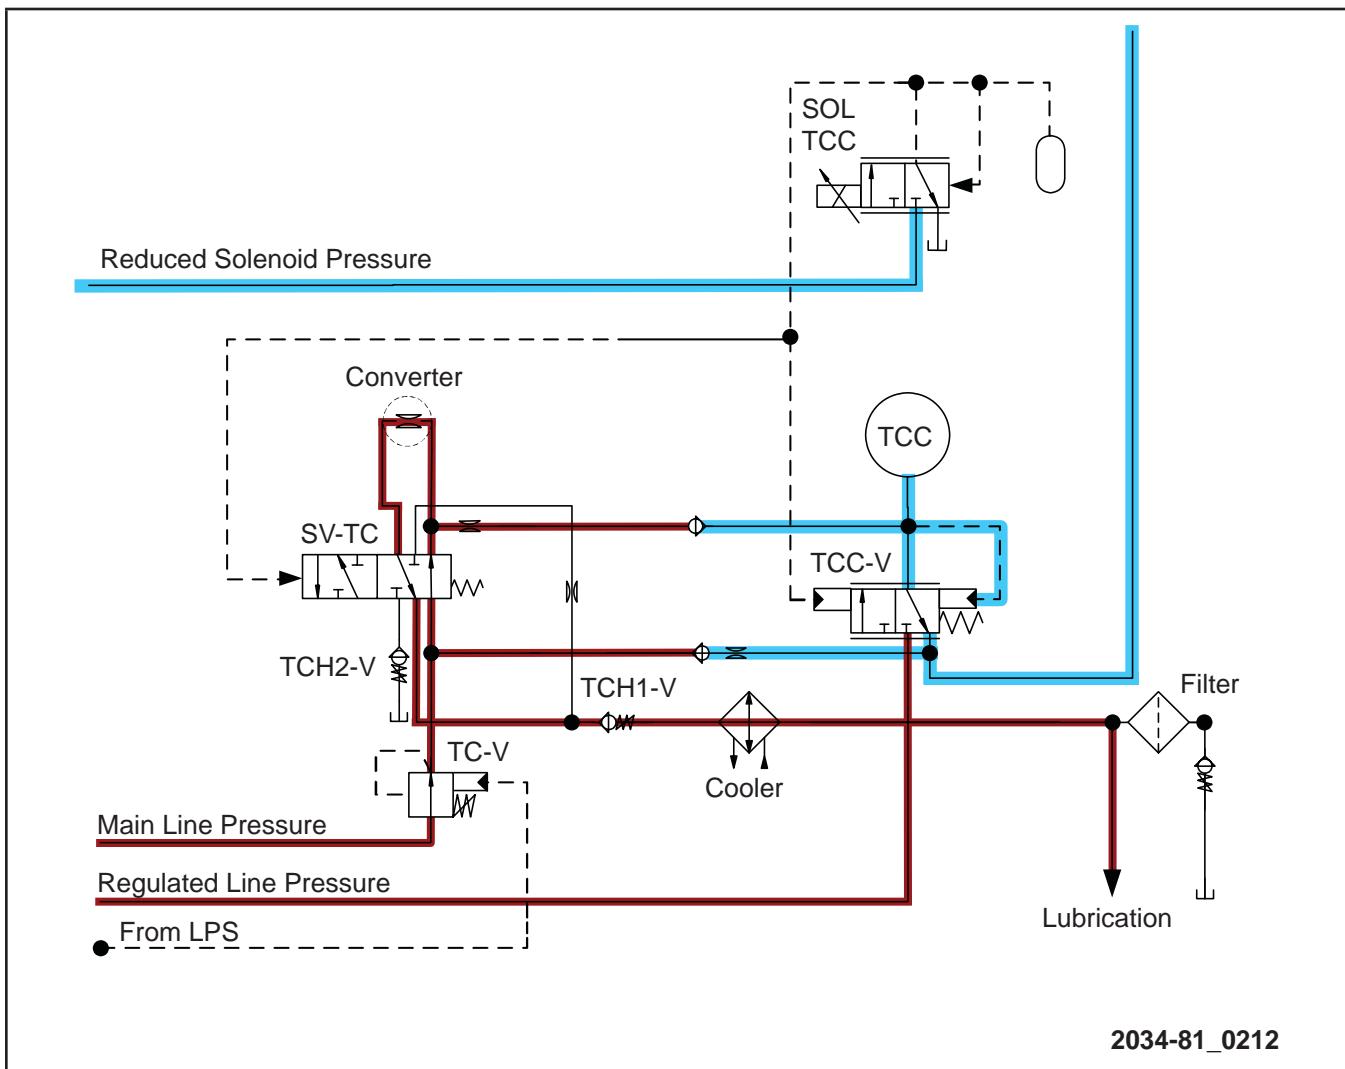

Figure 38 TCC Release

The torque converter clutch (TCC) is engaged and released by the transmission control module assembly (TCMA). The TCC can be engaged and controlled in any forward gear from 1st through 8th.

When the TCC is open, the TCC piston is pushed to its default position by torque converter chamber pressure. The torque converter switch valve (SV-TC) provides pressure for torque converter operation that has been regulated by the torque converter pressure valve (TC-V). After exiting the torque converter, fluid moves into the cooling and lubrication circuits. The converter pressure retention valve (TCH1-V) ensures the torque converter pressure is a minimum of 0.35 bar (5 psi) when the TCC is open.

8-Speed Hydro-Mechanical Systems Operation

TCC Apply

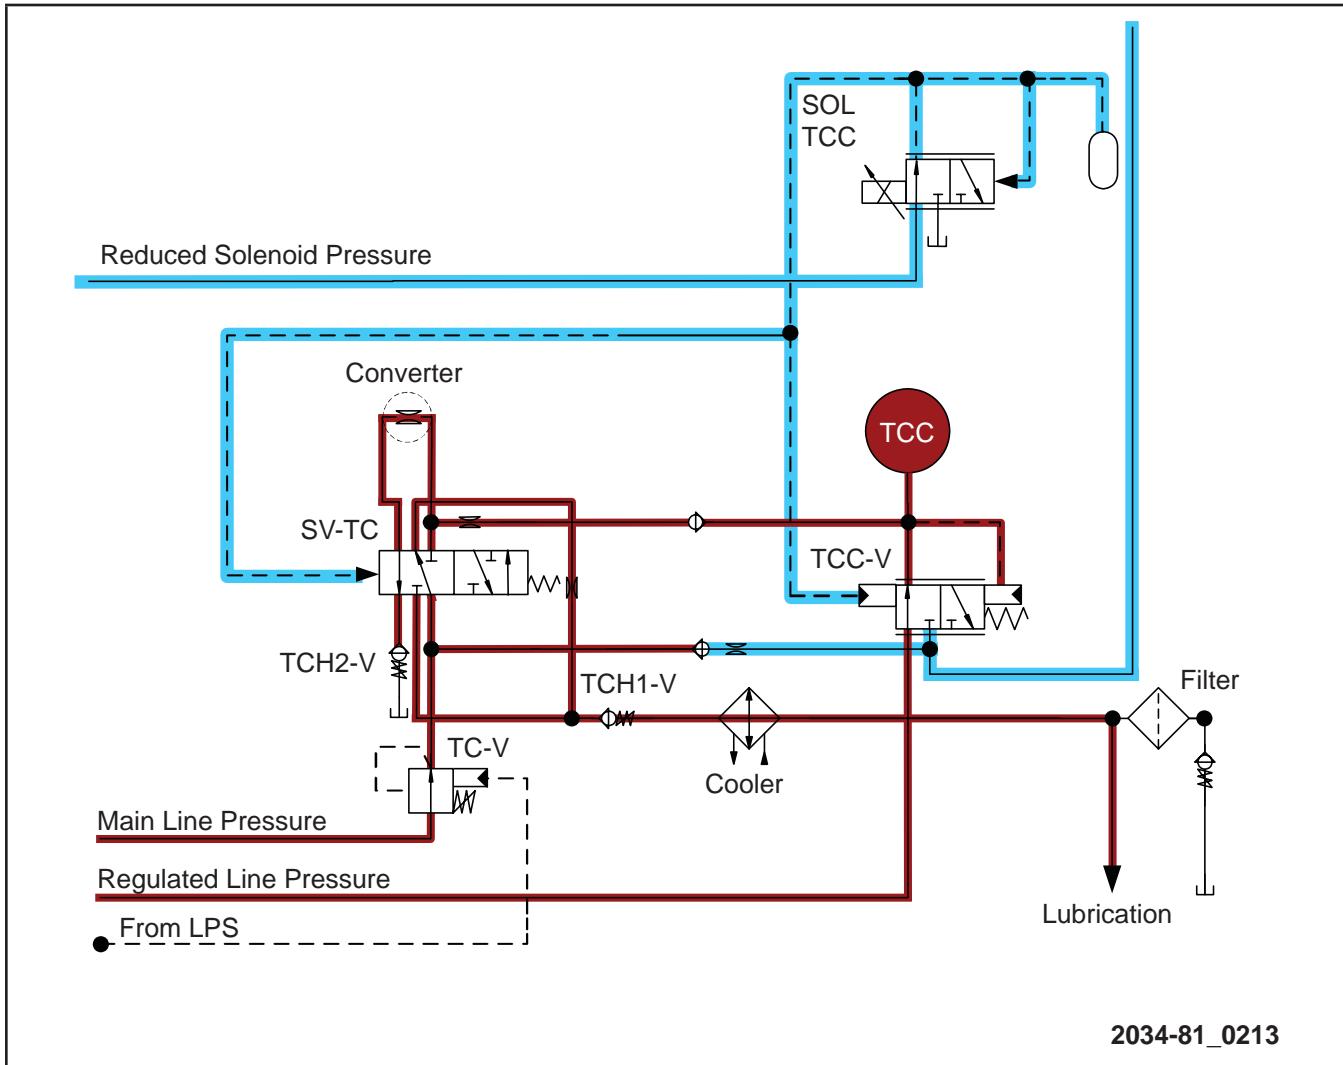

Figure 39 TCC Apply

When the TCC solenoid is energized, fluid is directed to the torque converter switch valve (SV-TC) and TCC lockup valve (TCC-V). The TCC lockup valve directs fluid to the TCC and torque converter chamber. The torque converter switch valve directs fluid exiting the converter chamber to a secondary pressure retention valve (TCH2-V) that is calibrated to retain 1.0 bar (14.5 psi) of pressure in the converter. The torque converter switch valve also directs line pressure to the cooler and lubrication circuit.

C Clutch Hydraulic Operation

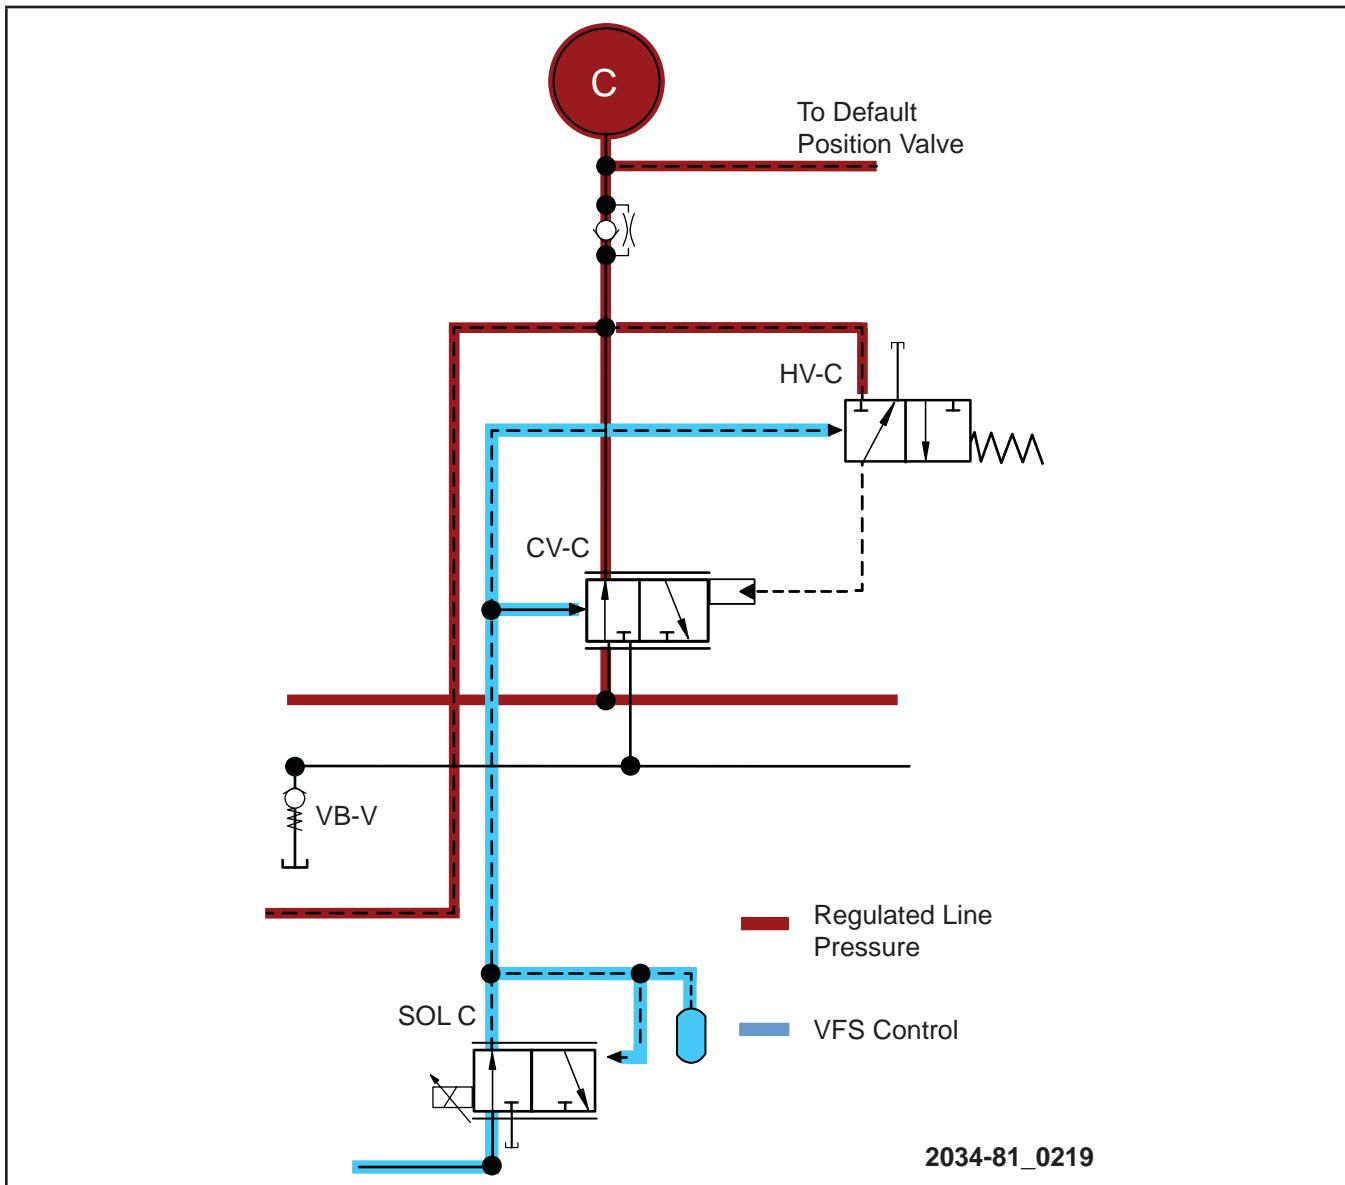

Figure 40 C Clutch Hydraulic Operation

Clutches C, D, and E all operate in a similar manner. Regulated solenoid pressure is available at the C clutch shift solenoid (SOL C) and regulated line pressure at the clutch valve (CV-C).

When the shift solenoid is de-energized, fluid flows through the shift solenoid and applies pressure to the clutch valve. During the shift, pressure moves the clutch valve, which begins to apply the clutch. Pressure from the holding valve (HV-C) regulates the opening of the clutch valve, softening the shift. Above a set threshold, the holding valve seats and allows the clutch valve to open completely.

8-Speed Hydro-Mechanical Systems Operation

B2 Clutch Hydraulic Release

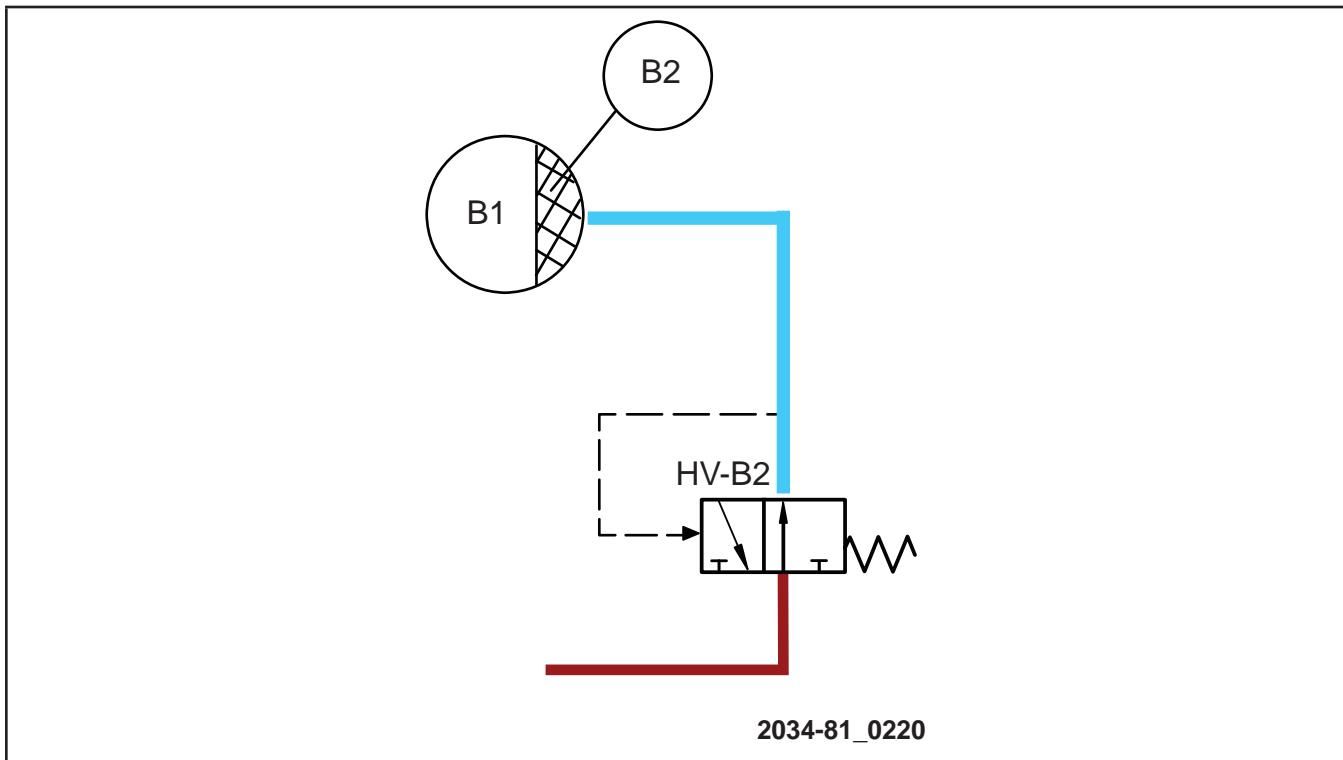

Figure 41 B2 Clutch Hydraulic Release

The B clutch includes two hydraulic chambers: B1 and B2. B1 is the B clutch apply circuit and B2 is the release circuit.

The holding valve (HV-B2) maintains regulated pressure against the release side of the B clutch. B2 fluid pressure remains constant at around 1.9 bar (27.6 psi) during normal operation. This constant pressure works against the B1 apply circuit pressure. The B2 circuit eliminates the need for a return spring. By using a hydraulic return instead of a spring return, the TCM has more accurate control of the B clutch slip during neutral idle control (NIC).

B1 Clutch Hydraulic Apply

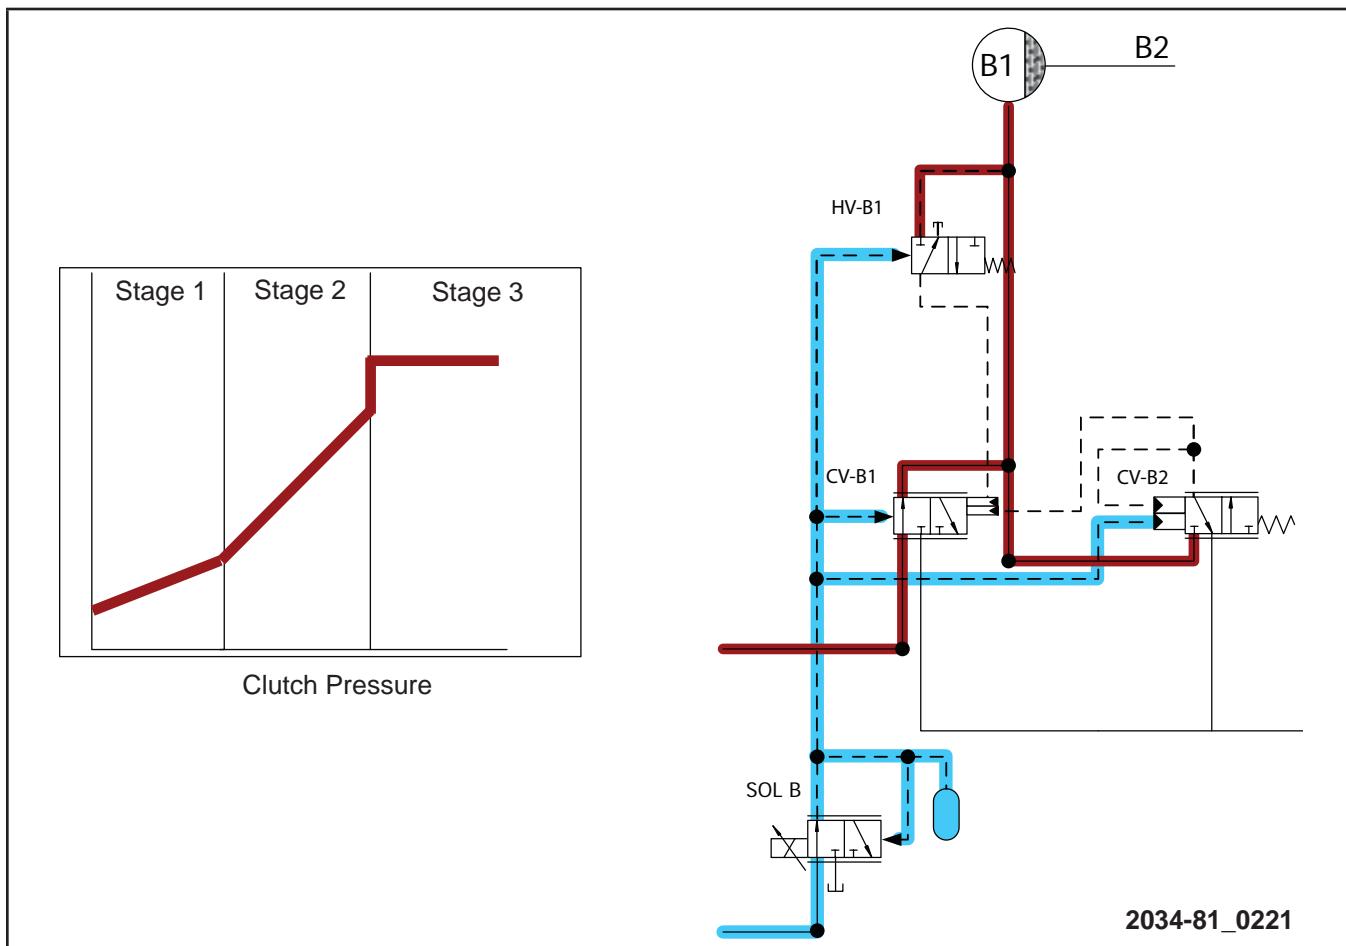

Figure 42 B1 Clutch Hydraulic Apply

When solenoid B is energized, regulated pressure flows through the solenoid and actuates the B1 clutch valve (CV-B1), B2 clutch valve (CV-B2), and B1 holding valve (HV-B1).

During stage 1, the B1 clutch valve opens, directing line pressure to the B1 side of the piston. The B2 clutch valve maintains pressure against the back side of the B1 clutch valve to control the initial engagement of the B clutch.

During stage 2, the B2 clutch valve seats and allows pressure in the B1 circuit to rise.

During stage 3, the B1 holding valve seats and allows full line pressure to keep B clutch applied.

8-Speed Hydro-Mechanical Systems Operation

Park Lock Hydraulic Operation

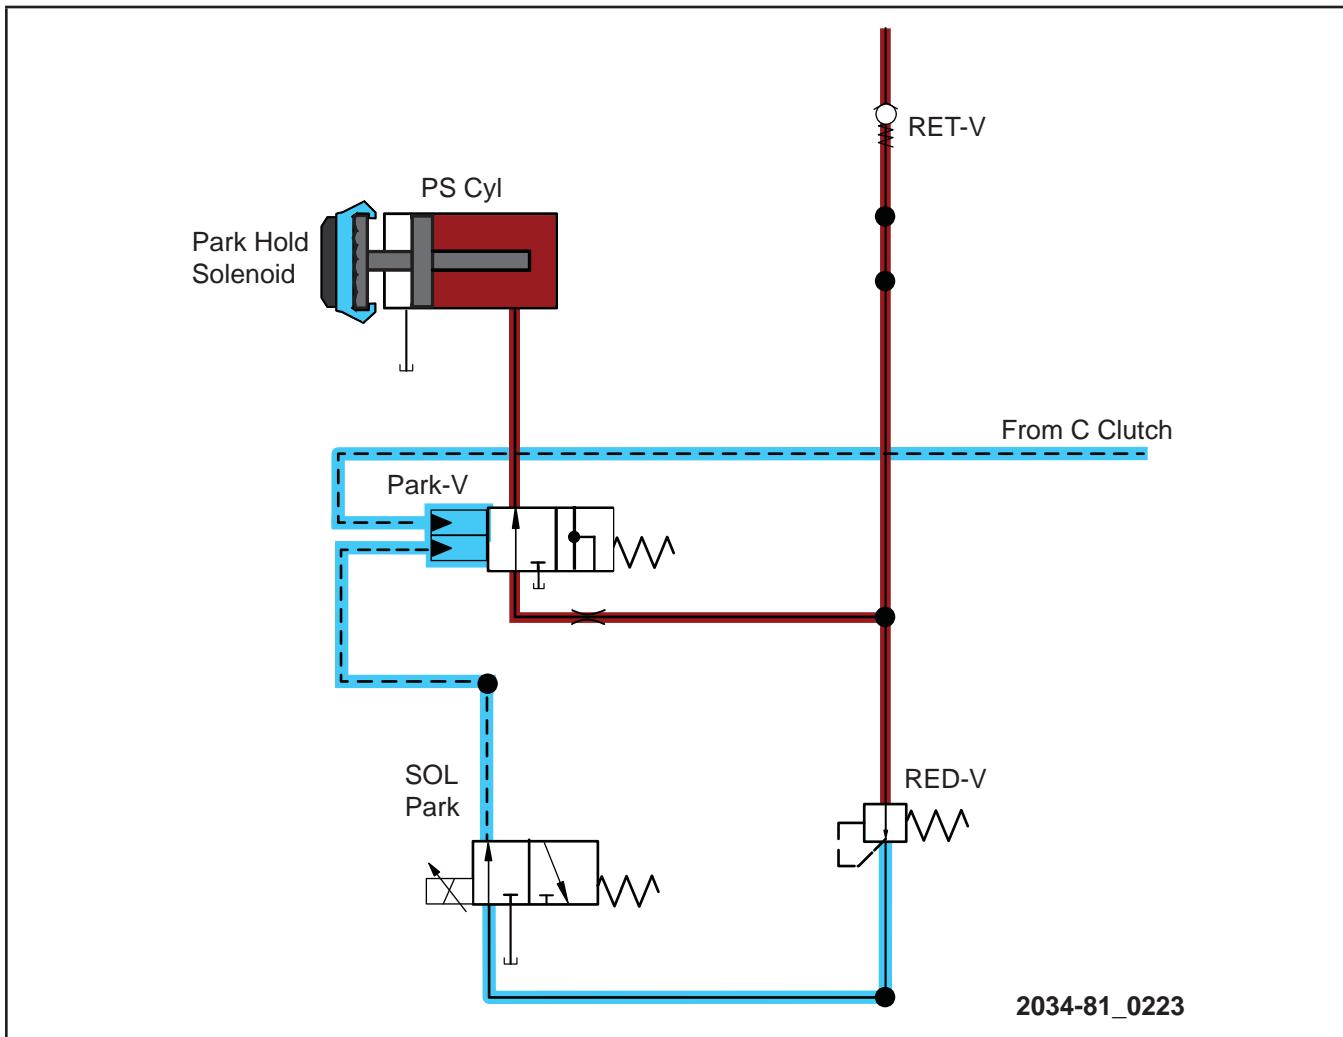

Figure 43 Park Lock Hydraulic Operation

In the default position, the park pawl is engaged. When the shifter is moved out of park, the park release solenoid (SOL Park) is energized and directs pressure to the park release valve (Park-V). The park release valve directs main line pressure to the park release cylinder (Park Cyl), releasing the park pawl.

In addition, the park hold solenoid is energized and holds the park release piston mechanically. The mechanical solenoid remains energized to hold the transmission out of park. This action is necessary because the fluid pressure drops as a result of the pump not operating with the engine off.

Position Valve Operation

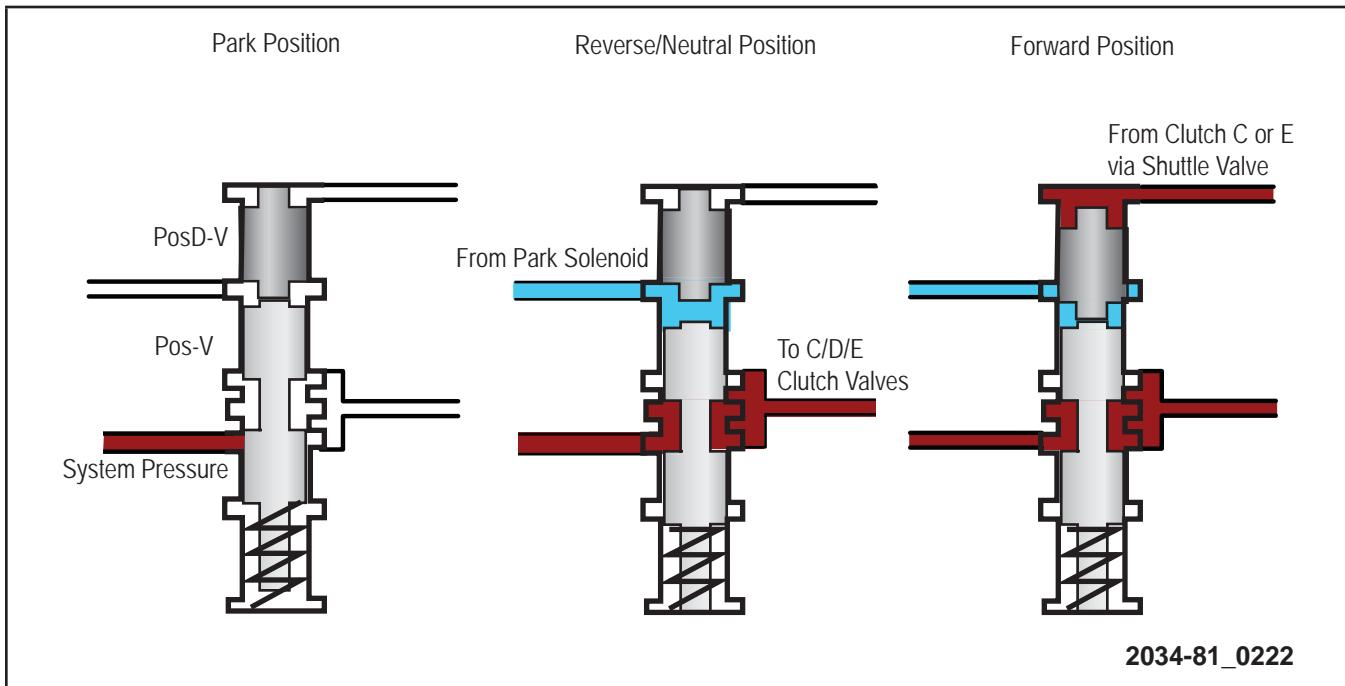

Figure 44 Position Valve Operation

Two position valves are used in the valve body. These valves supply the pressure to the C, D, and E clutch valves. The position valves are designed to supply pressure to the driving clutches and to maintain pressure in the driving clutch circuits if an electrical failure occurs.

When the shifter is moved to neutral or reverse, the park release solenoid supplies regulated pressure to the position valve (Pos-V). The position valve seats and supplies pressure to the driving clutch circuits.

When the shifter is moved to drive, clutch pressure from the C and E clutches is shared with a circuit that acts on the default position valve (PosD-V). When the default position valve is seated, pressure is maintained by the C and E clutches. This ensures that forward motion can be maintained even if the park release solenoid fails.

8-Speed Hydro-Mechanical Systems Operation

Default Operation

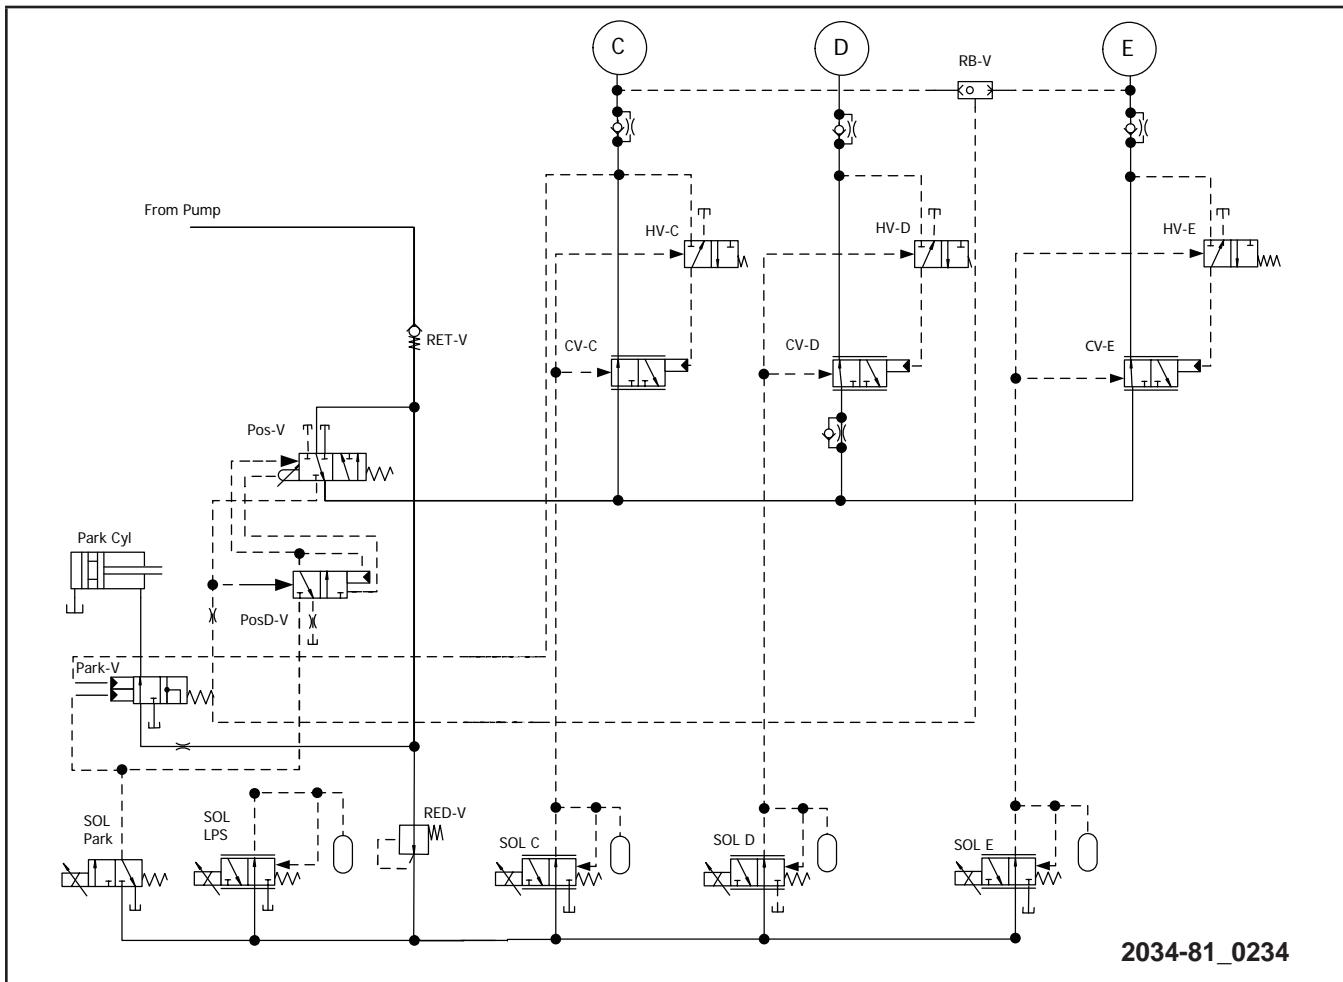

Figure 45 Default Operation

If a TCM failure occurs (or complete solenoid power loss) while driving in a forward gear, the C or E clutch circuit maintains hydraulic pressure against the park release valve. Pressure from either the C or E clutch circuit through the rocker ball valve (RB-V) keeps the default position valve (PosD-V) and position valve (Pos-V) open. The position valves maintain fluid pressure to the C, D, and E clutches, and 6th gear is engaged.

If the vehicle is turned off and a TCM failure is still present, the vehicle will not be able to move. This is because the fluid that feeds the C, D, and E solenoids cannot be supplied through the POS-V.

Priming Circuit

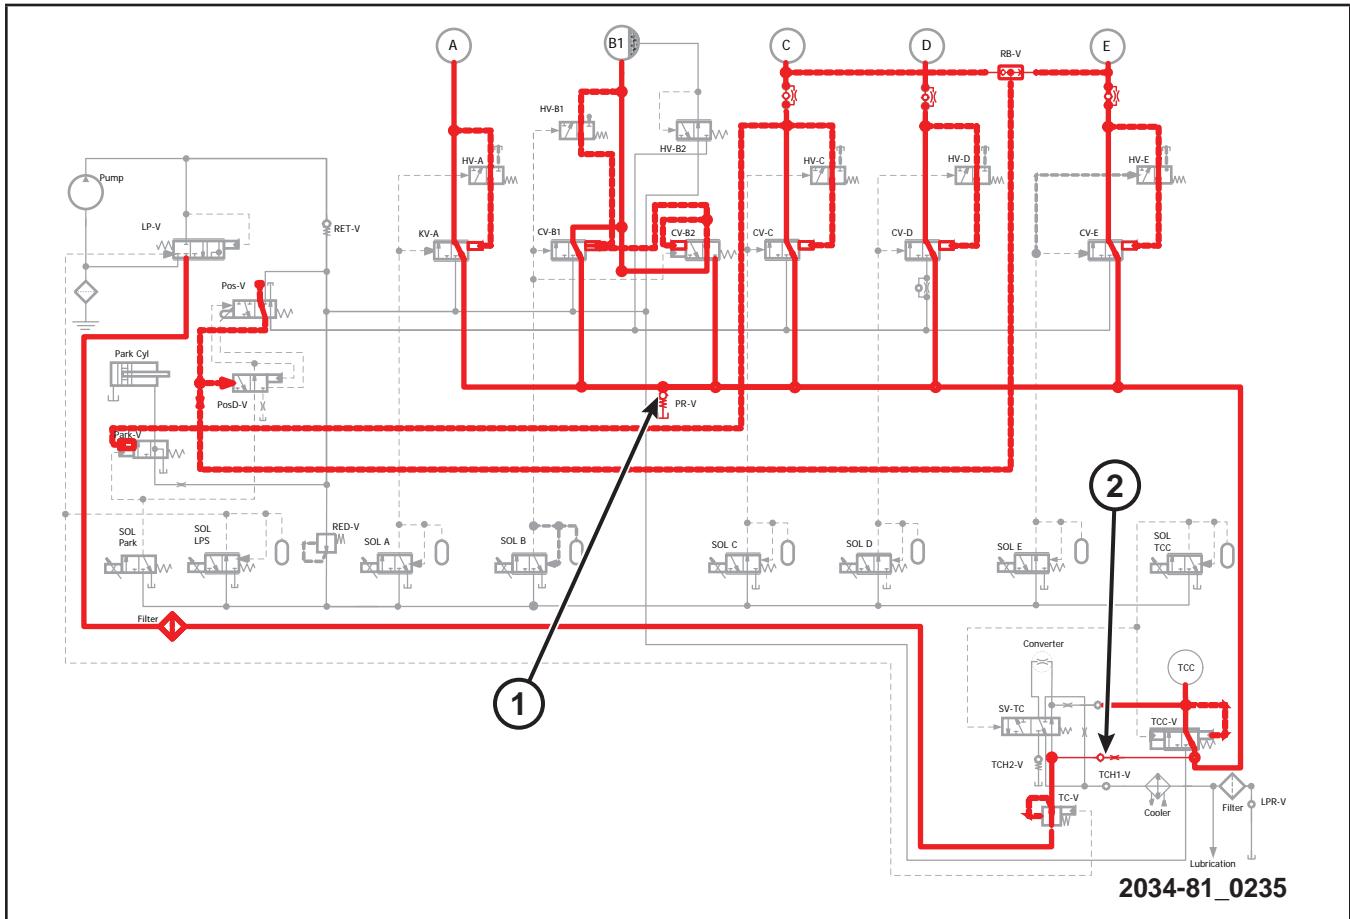

Figure 46 Priming Circuit

The priming circuit pre-fills the clutches with low-pressure fluid and resets the apply and holding valves to their default position.

The priming circuit is fed through a check ball and orifice from the torque-converter-regulated pressure circuit. The priming valve (PR-V) ensures that pressure remains low enough to prevent the clutches from engaging.

LESSON 4 8-SPEED ELECTRICAL OPERATION

ELECTRICAL INPUTS

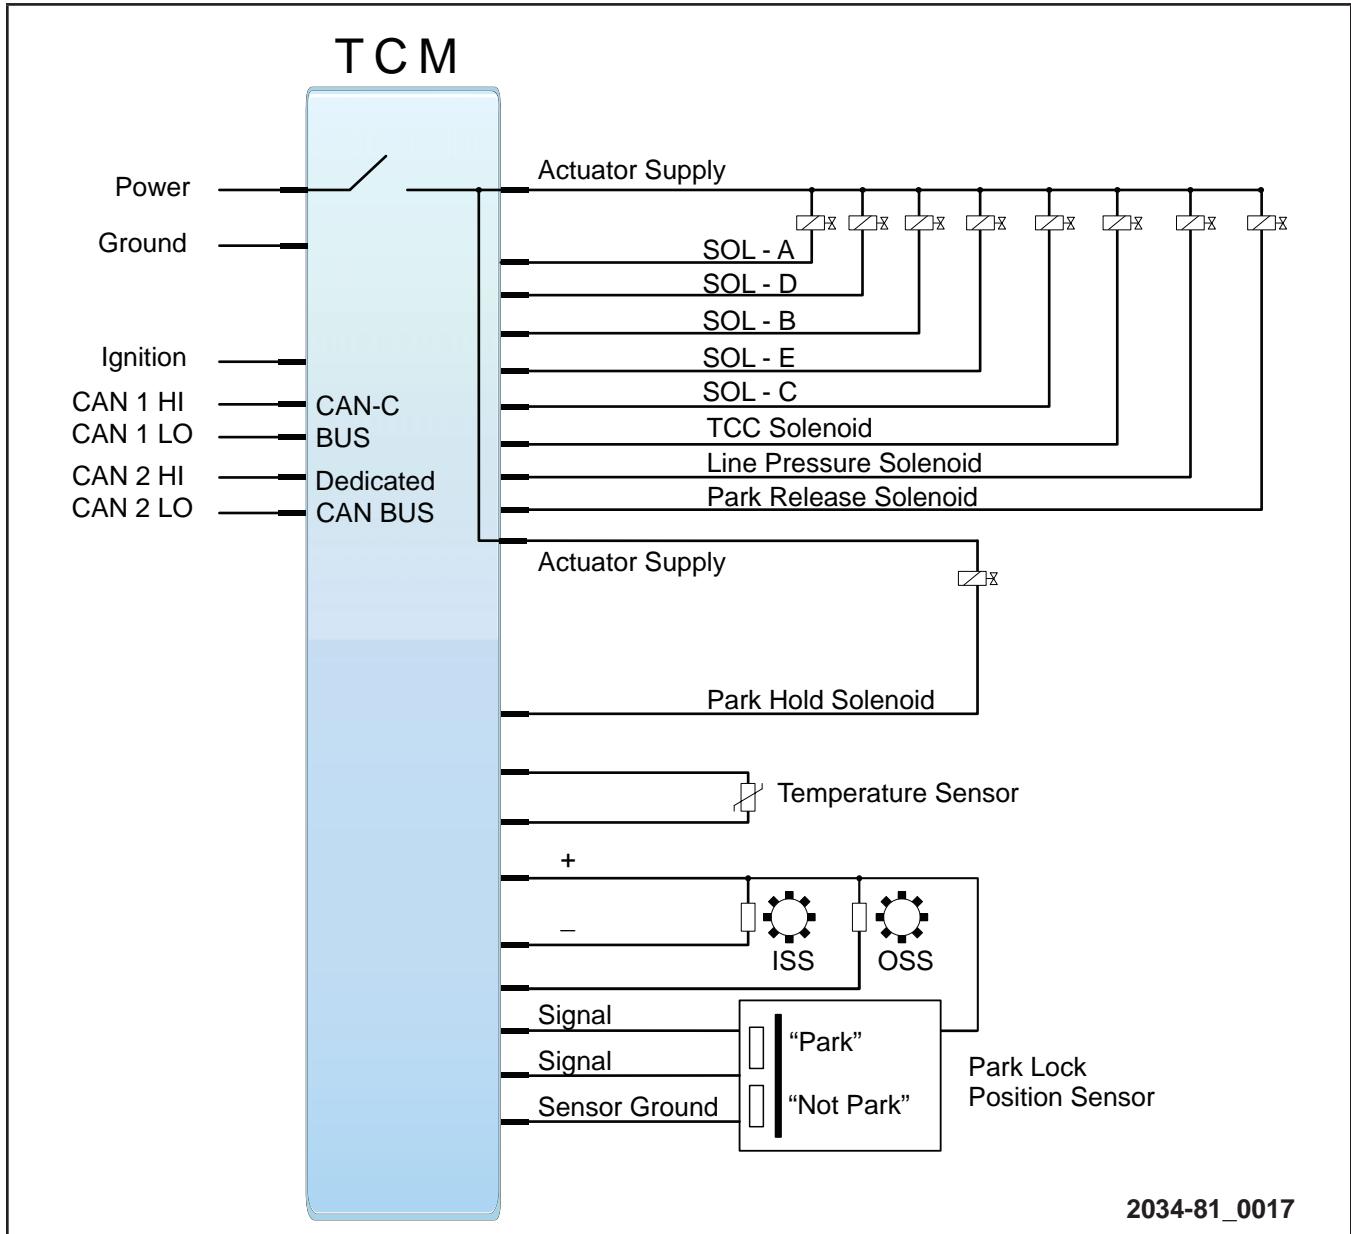

Figure 47 Transmission Control Module (TCM)

8-Speed Electrical Operation

Transmission Control Module (TCM)

The TCM receives drivability data from the powertrain control module (PCM) and other modules over the CAN-C network. It also receives shift lever position information from the electronic shifter over a dedicated transmission CAN network. The TCM uses four sensors that are integrated into the valve body assembly. The TCM processes this input data and controls operation of the torque converter clutch, park lock system, solenoid valves, and pressure regulating valves.

Speed Sensors

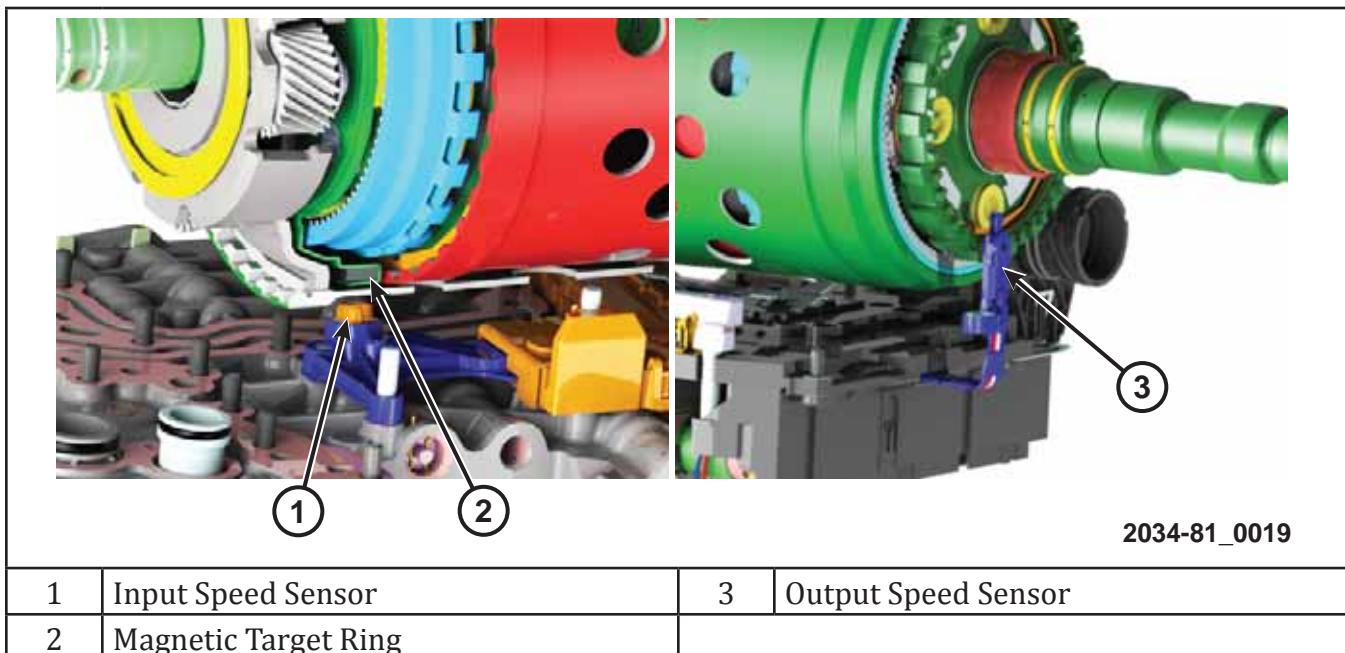

Figure 48 Speed Sensors

The input speed sensor (ISS) and output speed sensor (OSS) are Hall-effect sensors that measure shaft rotational speed.

The ISS is located at the front of the TCMA and reads input shaft speed from the magnetic ring on the P2 carrier.

The OSS is located at the back of the TCMA and reads output shaft speed from the P4 carrier.

8-Speed Electrical Operation

Temperature Sensor

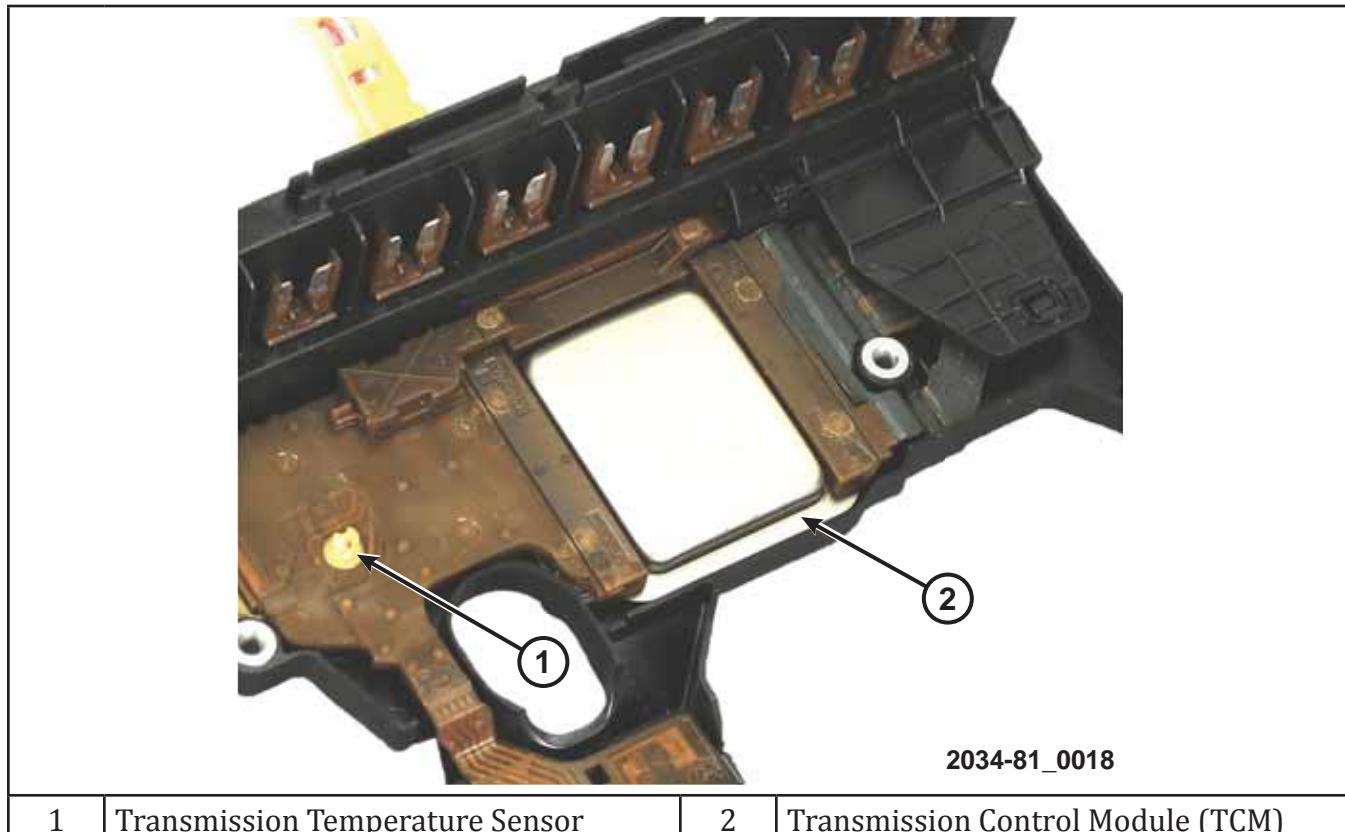

Figure 49 Temperature Sensor

The transmission oil temperature sensor is a thermistor that measures the temperature of the transmission fluid in the case. The transmission oil temperature sensor is mounted under the solenoids on the TCMA.

The TCM also contains an internal temperature sensor. The TCM compares the internal temperature reading with the fluid temperature sensor to determine hot mode strategy.

NOTE: The TCM internal temperature sensor can be viewed on the scan tool.

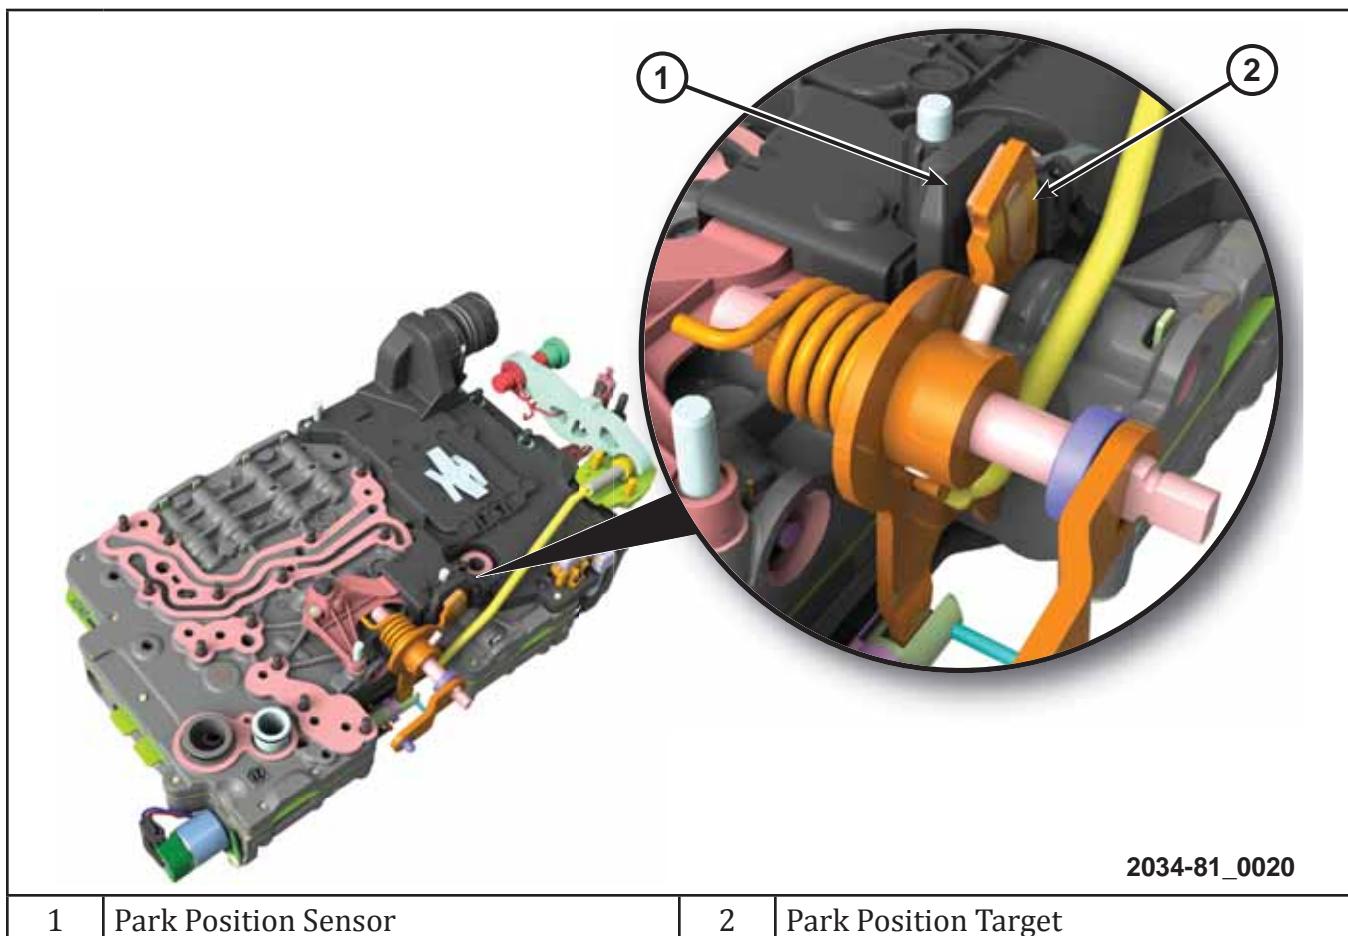

Park Position Sensor

Figure 50 Park Position Sensor

The park position sensor is a digital sensor that monitors the position of the park pawl linkage. The sensor target is located on the park selector shaft. There are two digital Hall-effect sensors built into the TCMA that monitor the position of the target on the park selector shaft.

8-Speed Electrical Operation

ELECTRICAL OUTPUTS

Solenoid Operation

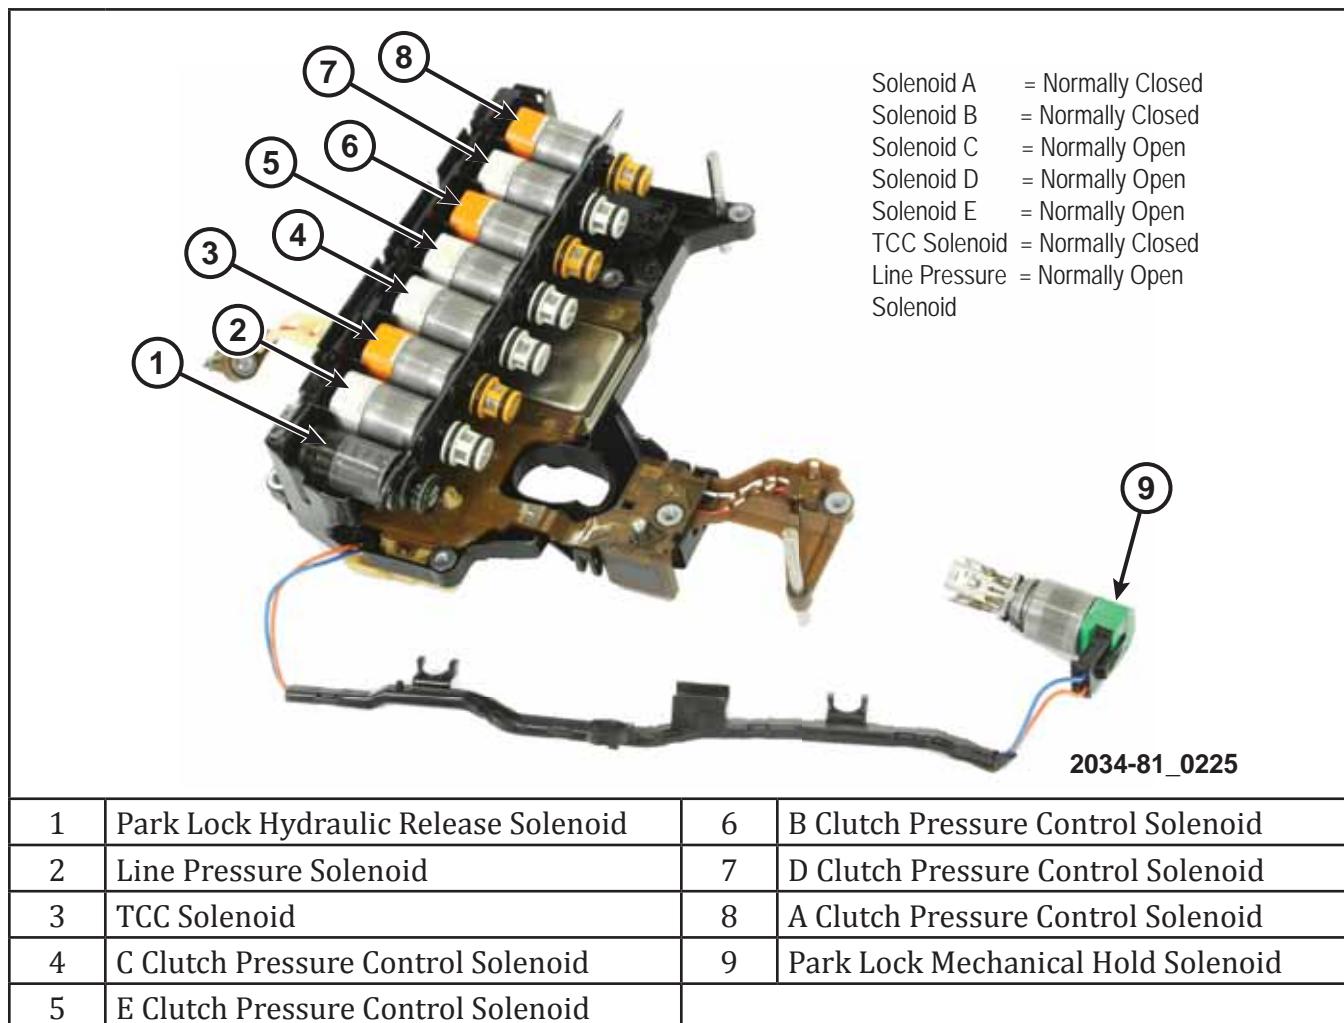

Figure 51 Solenoid Operation

Shift solenoids A through E, the TCC solenoid, and the line pressure solenoid are all variable force solenoids that are controlled by the TCM via pulse-width-modulated signals. Variable force solenoids allow the TCM to control the amount of fluid pressure in the hydraulic circuit. These solenoids are identified as normally-open (NO) or normally-closed (NC) based on their hydraulic position when de-energized.

The park release solenoid is a normally-closed, ON/OFF solenoid. When the park release solenoid is energized, it directs fluid pressure to the park release cylinder to disengage the parking pawl.

The park hold solenoid is an ON/OFF, mechanical solenoid. When the park hold solenoid is energized, the mechanical claws of the park hold mechanism grab the end of the park release piston and hold it to prevent the park lock pawl from engaging. The park hold solenoid is energized any time the engine is running and the shift lever is in any position except park. In addition, the park hold solenoid remains energized if the engine is turned off while the shifter is in neutral (car wash function).

MODULE COMMUNICATION AND CONTROL STRATEGIES

Module Communications

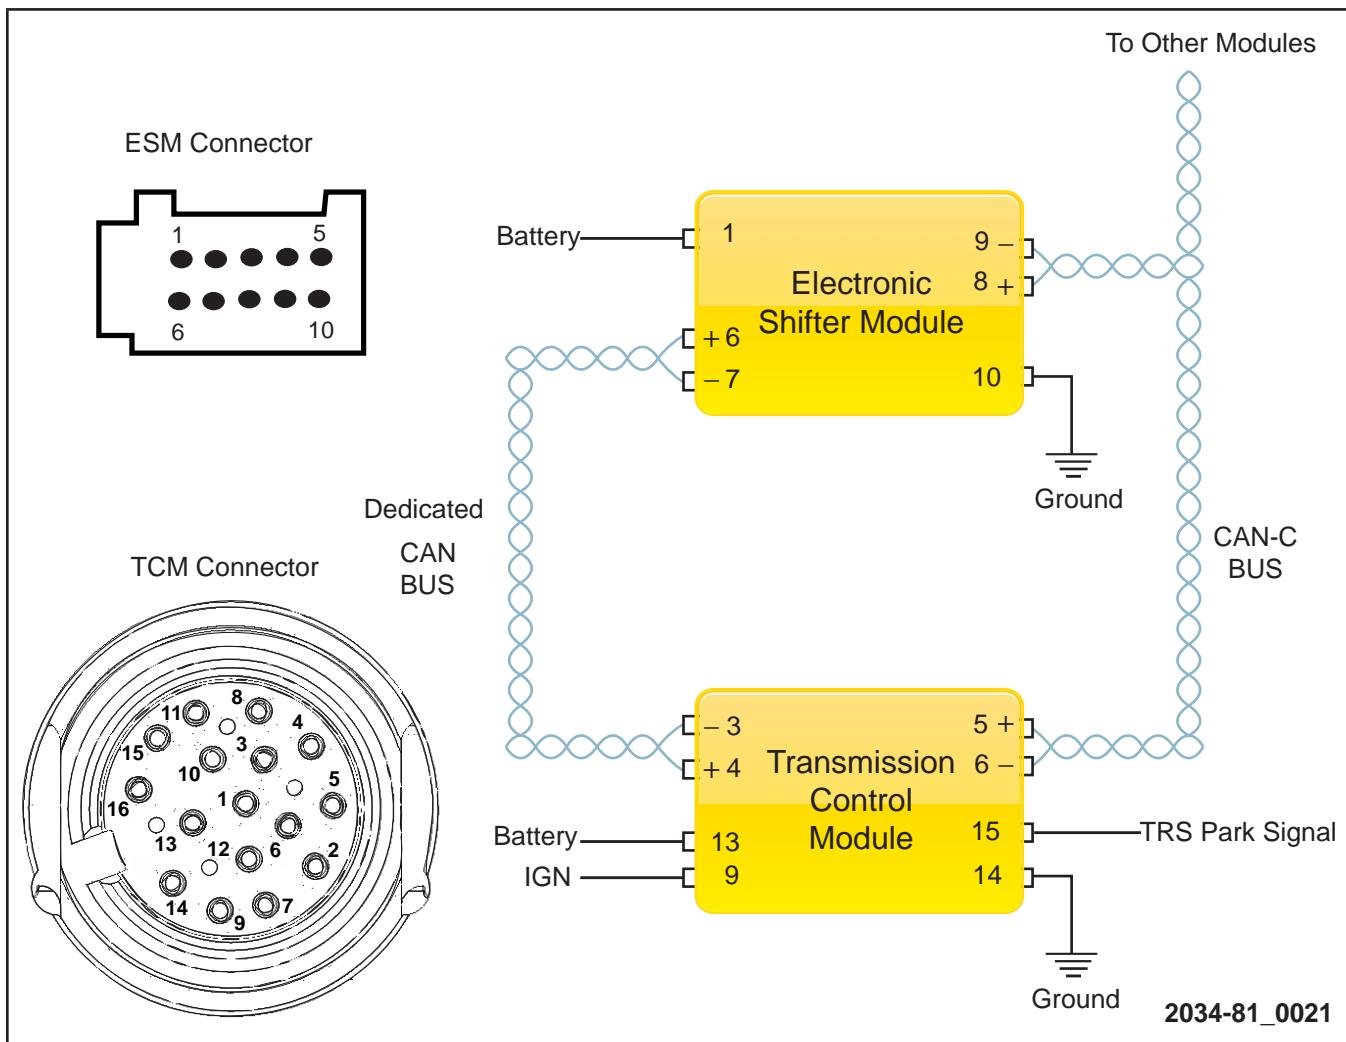

Figure 52 Module Communication

The 8HP45 transmission uses a shift-by-wire system with an electronic shifter. The electronic shifter includes battery voltage and ground circuits, CAN-C network circuits, and dedicated CAN circuits for direct communication of requested shift lever position to the TCM.

The messages communicated on the dedicated CAN network are redundant to messages also sent over the CAN-C network. This helps maintain the integrity of the system during certain failures.

8-Speed Electrical Operation

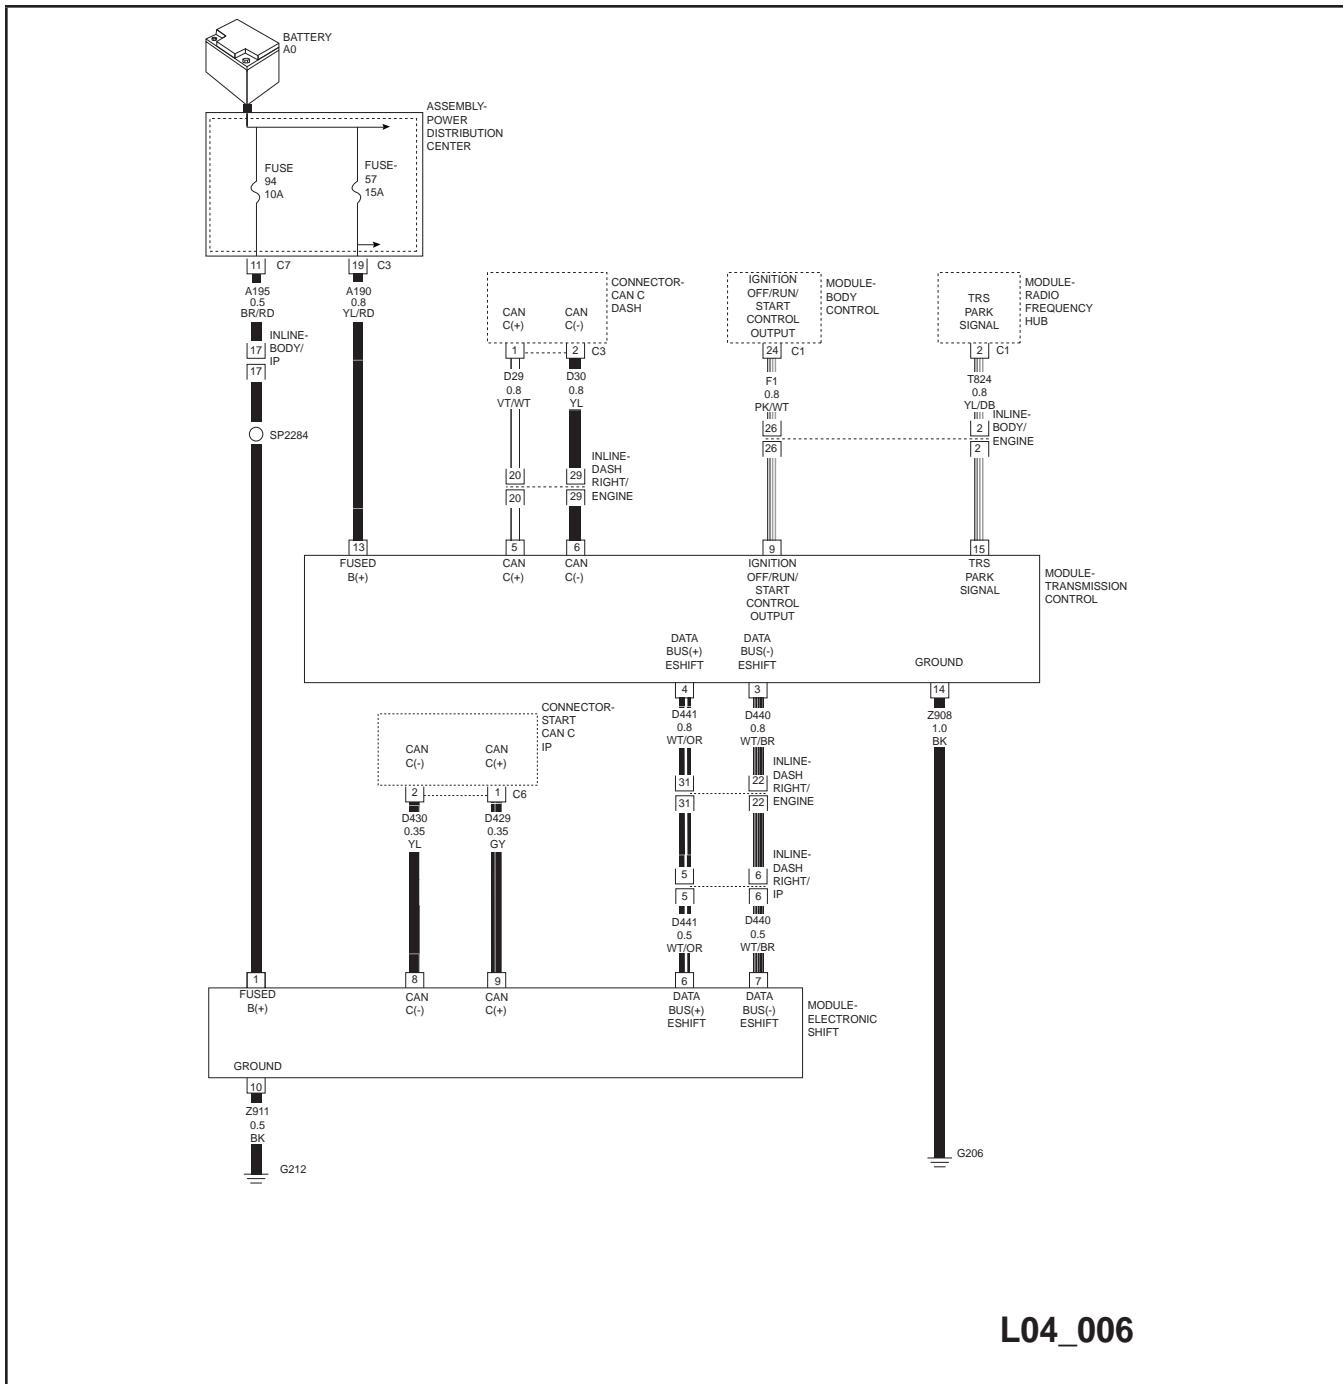

Figure 53 8-speed Wiring Diagram

Adaptive Strategies

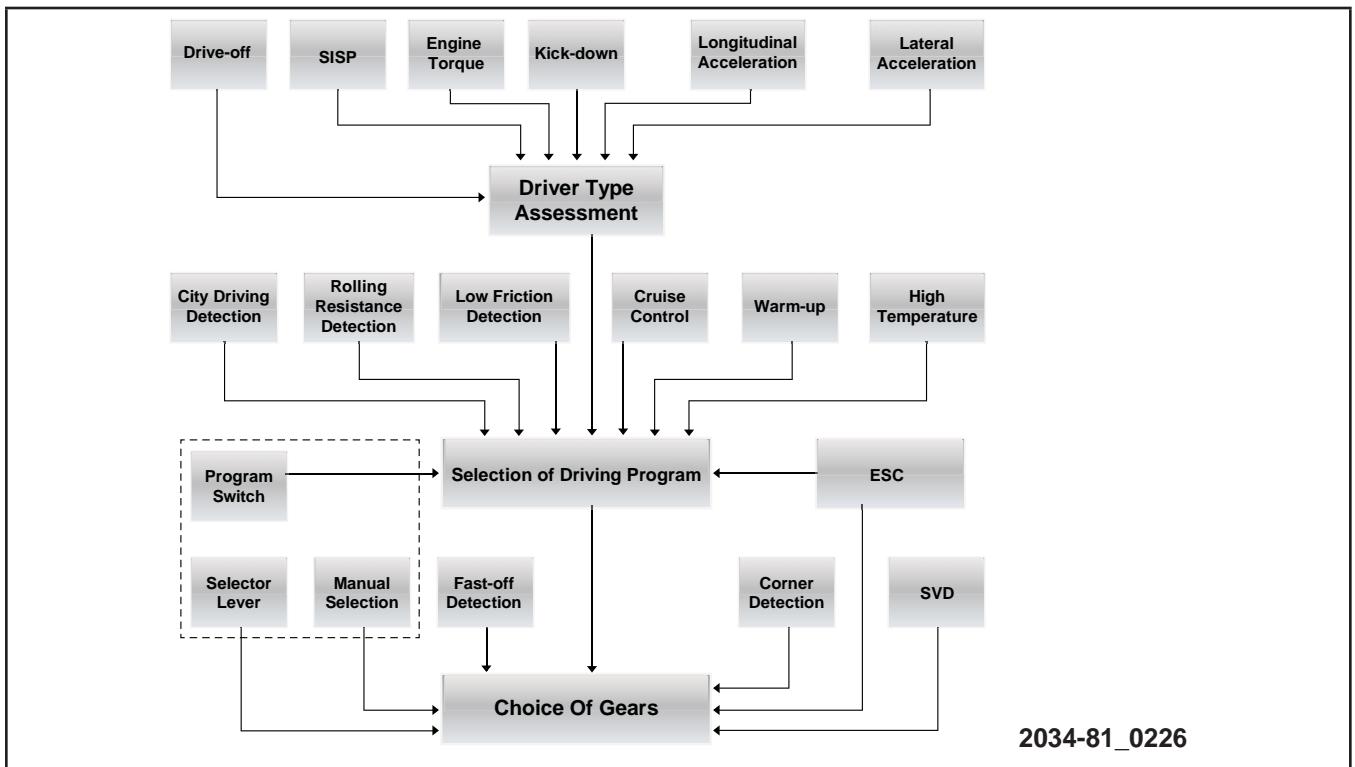

Figure 54 Adaptive Strategies

The TCM evaluates driving styles and current conditions and compares this data to stored shift programs. The TCM controls transmission shift operation dynamically by choosing an appropriate strategy. The TCM can calculate the amount of drag to determine shift programs based on ascending, descending, or level driving.

8-Speed Electrical Operation

Neutral Idle Control

Neutral idle control (NIC) is a transmission strategy that disengages the transmission when the vehicle is stopped with the transmission in a forward gear range. Disengaging the transmission at a standstill is accomplished by allowing a controlled slip of the B clutch. The amount of slip is determined by calculating the difference between engine speed and transmission turbine speed. To ensure that the vehicle can drive off without delay, the power flow is not completely disengaged. A small amount of torque is always transmitted. In addition, the C clutch is closed to accept power flow before the driver accelerates. When combined, these strategies also minimize the risk of rolling backwards on hills.

If a predetermined accelerator pedal angle value is exceeded, rotation of the output shaft is detected, or the brake pedal is released, neutral idle control is deactivated.

Drag Recognition Strategy

The calculation of drag is based on a balance between engine torque and friction on the drive wheels. Tire rolling resistance, vehicle weight, wind resistance, and gradient resistance all play a role in the drag calculation. The TCM uses drag calculations to adjust transmission shift points for all conditions that increase or decrease the apparent load.

Cruise Control Strategy

When cruise control is selected, the set driving speed is held constant and the TCM utilizes the drag calculation to determine the correct strategy to maintain the set speed.

Warm-Up Strategy

The warm-up strategy is selected when engine coolant temperature is below 30 °C (86 °F). During warm-up, neither the driver-type evaluation nor drag calculation are active. The warm-up strategy is disabled temporarily when driving downhill or when kickdown is necessary.

High Temperature Strategy

The high temperature strategy is enacted when transmission oil temperature rises above 120 °C (248 °F). When the high temperature strategy is active, the red transmission control indicator illuminates and the temperature level is central to the calculation of shift points.

The high temperature strategy includes delaying shifts and changing the torque converter clutch lockup strategy to help provide a non-slip direct-drive in the transmission for as long as possible to assist in transmission fluid cooling.

Low Friction Strategy

When low friction road surfaces are detected, the TCM selects a higher gear. In addition, when low friction surfaces are detected at higher speeds, the TCM will avoid downshifting to minimize the risk of shift-induced traction loss. The TCM also receives wheel slip data and can immediately change gear without driver interaction.

Stability Control Strategy

In addition to wheel spin control, the TCM also adjusts shift strategies based on stability control signals from the ABS module and the PCM. The TCM can suppress gear shifts or alter shift characteristics to assist in controlling vehicle slide.

GLOSSARY

adaptive strategies	Dynamic control over shift operation based on driving conditions and driver input.
car wash function	A strategy to keep the park lock disengaged when the engine is shut off with the electronic shifter in neutral.
cavitation	The formation of cavities or bubbles in a fluid that is being pumped. This occurs when the fluid level is too low and the inlet pipe draws air into the pumping system. This can also occur when the fluid level is too high and contacts the rotating components of the gear train (think of beating an egg with a whisk).
contact point pressure	The pressure necessary to fill the B1 clutch piston to allow it to just touch the release point.
controlled slip	Regulated amount of slip on the B clutch in neutral idle control.
de-energized	Meaning that an electrical solenoid is not being supplied any current.
double-stroke vane pump	A dual inlet and outlet chambered positive-displacement pump that consists of vanes mounted to a rotor that turns inside of a cavity.
electronic shifter	The electronic shifter system that uses sensors and bus communication instead of a traditional shift cable to control direction of movement.
electrostatic discharge	The human body, if electrically charged but not properly grounded, discharges an electrostatic spark (this endangers electronic components).
filled-for-life	Transmission fluid maintenance strategy stating: under normal operating conditions it is not necessary to check the fluid level or change the fluid and filter.
gear reduction	The input speed is higher than the output speed, increasing torque.
Hall-effect sensor	A transducer that varies its output voltage in response to a magnetic field.
holding clutch	A clutch that is splined to the case. When applied, the clutch causes a member of the gear set to stop rotating.
holding valve	Regulates the opening of the clutch valve to control shift feel.
molded lead frame	Molded plastic formed to the valve body that contains the internal harness and sensors.
multi-disc clutch pack	Type of clutch that has several driving members stacked with several driven members. Consisting of alternating steel and friction discs.
neutral idle control	A transmission strategy that disengages the transmission from engine torque when the vehicle is at a stop in a forward gear range.
position valve	Supplies hydraulic pressure to the driving clutches and maintains pressure in the driving clutch circuits if an electrical failure occurs.
rotating clutch	A clutch that is housed in a rotating drum or housing and provides input torque to the gear train.
Simpson gear set	A planetary gear set consisting of two planetary gear sets that share a common sun gear.

torsional vibrations	Angular vibration of an object, such as the components transmitting the torque, can generate non-smooth or alternating torques. The components in the transmission are not infinitely stiff, these alternating torques cause vibration around the axis of rotation.
transmission control module assembly (TCMA)	The TCMA includes the transmission control module, the molded internal wire harness, and the four input sensors.
variable force solenoid	A solenoid that is controlled by a pulse-width-modulated signal to control the amount of fluid pressure in a hydraulic circuit.
